VOL XXXI CHICAGO, ILLINOIS, SEPTEMBER 3, 1898 No 10

ADDRESSES

THE INFLUENCE OF AGE, SEX AND RACE IN SURGICAL AFFECTIONS

Address of the Chairman of the Section on Surgery and Anatomy, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo, June 7-10, 1898

BY WM L RODMAN, M D
LOUISVILLE KY

Gentlemen of the Section —Allow me first to express my grateful appreciation for the honor conferred upon me at the Semi-Centennial Meeting To be chosen as Chairman of this, the largest Section of the ASSOCIATION, is indeed an honor any one should esteem highly

I have endeavored, with the aid of the distinguished Secretary, Dr Parkhill, to present to you as attractive a program as has ever been offered to this or any other Section in former years Indeed, too much credit can not be given our Secretary for his indefatigable labors and their fruitful results We regret that his obligations to our country, now resounding from end to end with stern alarums, deprive us of his companionship and help on this occasion, to which he has looked forward with such keen pleasure, and for the success of which he is so largely responsible I am sure that I voice the sentiments of every member of the Section, when I thank him for his work in our behalf, and bespeak for him a safe return to Denver, where his professional worth and surgical skill have long been recognized as second to none Our loss is the country's gain, and we might well wish that all of our countrymen needing surgical attention in the pending war with Spain, may fall into hands as competent and deft as the Surgeon of Colorado's Volunteer Corps

We also wish to express our gratitude to Dr Powers, the Acting Secretary, who on short notice assumed the work and gave to it most intelligent and conscientious attention

In offering for your consideration the customary Chairman's Address, I have chosen for my subject "The Influence of Age, Sex and Race in Surgical Affections" Time limits will prevent consideration of all diseases having a bearing upon the subject, and your attention will, therefore, be asked to some affections seeming to have a pointed claim to our notice

The treatment of racial differences has been almost necessarily limited to the white and black races of North America, as but few of the many army and navy surgeons to whom I have written for data gathered by them in their various assignments, have been able to reply at satisfactory length on account of the exacting demands of the past three months

The diseases of the negro possess an abiding interest to those of us living in the South, called upon as we are daily to give him professional succor in private, hospital and dispensary practice Although much that is of value has been written of his immunities and susceptibilities to disease, it has occurred to me that the last word has not been spoken, due more to the changes in the negro himself than to inaccurate observations on the part of medical writers of the past and present

In To the careful student who reviews the literature of the subject, there is no escape from the conclusion that the negro as we now find him, with changed environments, habits and associations, is a different being from what he was in antebellum days He came to America three hundred years ago with certain immunities and susceptibilities to disease, which were so conspicuous as to be noted by all trustworthy observers A few of the immunities he hitherto enjoyed have been maintained, more have been lost in part, others wholly exhausted, and to some few diseases he shows not only the same liability as the Caucasian, but even exceeds him in vulnerability, to-wit local tuberculosis of glands, skin and bones The original susceptibilities of the negro seem to have abided with him, and to have undergone less change, he still being as obnoxious to fibroid and other benign neoplasms as he has ever been, as well as to keloid, elephantiasis and tetanus Not only is the race manifesting an increasing tendency to disease of all kinds, but statistics of every Southern hospital will prove them to be less resistant and to show a larger mortality, both in medical and surgical affections (operative and non-operative cases), than the Caucasian The full-blood is less resistant to begin with, and the mulatto inherits the weaknesses of both races, the strength of neither, and begins life with the heaviest of handicaps Therefore, it is not surprising to the observant to occasionally hear such authorities as Hunter McGuire, D W Yandell, and other thoughtful practitioners of large and long experience with this race, say that the African will in time become as extinct in this country as the bisons and the North American Indian It is clearly foreshadowed, that he can not maintain the struggle for life with a race his superior in every respect, in a climate to which he is ill-suited at best

MALIGNANT DISEASE

All early writers testified to the immunity of the African, in both his native and adopted country, to malignant disease It can not be doubted, I think, that as a race, cancer was most rare with them up to fifty years ago These early writings have too much influenced practitioners of this generation, however, and many reason that cancer is still rare with negroes, because such was undoubtedly the case a few generations ago

Malignant disease (both sarcoma and carcinoma) is certainly increasing in frequency in the black with even greater ratio than in the white race From a condition of practical immunity they have become nearly as liable to malignant disease of some organs as the white, quite as much so to that of the mammary gland and the seemingly more obnoxious cancer of the uterus The records of the City Hospital and Health Department of Louisville for the past thirty years are in line with the statements and statistical data of Billings and Matas, and emphasize especially the frequency of cancer of the uterus in negroes It would be interesting to know what per cent of the cases were in full-bloods, but it is impossible to ascertain this, as no distinction is made in our reports between full-bloods and mulattoes Nor is it possible to determine with reasonable accuracy the relative number of cases of sarcoma and carcinoma, and therefore, no attempt is made to do so

It is safe to say, however, that the negro is relatively somewhat more prone to sarcoma than cancer As has been stated, the mammary gland suffers as often in the black as in the Caucasian, the uterus more so Now it would appear *a priori*, that the negro, almost universally affected as he is with phimosis, should show a special susceptibility to cancer of the penis, yet I have never seen such a case, nor do the records of our city hospital indicate that one has been treated there in thirty years Of 207 deaths from cancer in negroes reported to the Louisville Health Department in thirty years, none have been entered as cancer of the penis

According to the eleventh census (just issued), malignant disease occurs in every 100,000 living inhabitants

Whites	53 93
Negroes	36 65
North American Indians	5 31
Chinese a little less liable than Indians	

To every 1000 deaths from known causes in the United States in persons over forty-five years of age, there were due to cancer and tumor

Whites	62 86
Negroes	29 81
North American Indians	14 49
Chinese	12 99

In this country, as in England, cancer is alarmingly on the increase Both races show a marked increment of gain, and so far as cancers in general are concerned, the increase has been about the same in the two races, as will be shown by the table giving every death from cancer in Louisville for thirty years These records have been gone over by my assistant, and are, I am sure, reliable, as he has devoted weeks to the work It will be seen that the number of cases has doubled each decennium

CANCER OF ALL PARTS

1868 to 1878—total number deaths 244 white 205 colored 39
1878 to 1888—total number deaths 484 white 411, colored 73
1888 to 1898—total number deaths 892 white 797, colored 95
Total number deaths for thirty years 1620 white 1413 colored 207

There have been 161 cancerous patients in the Louisville City Hospital during the past twenty years (1878 to 1898) The records of the decennium from 1868 to 1878 are incomplete and are therefore excluded Of cases admitted there were 118 white and 43 colored

1878 to 1888—total number cases admitted 63 white 47, colored 16
1888 to 1898—total number cases admitted 98, white 71, colored 27
1878 to 1898—total number cases admitted 161 white 118 colored 43

These statistics agree fully with those of Matas, drawn from the service of the Charity Hospital in *New Orleans, and show that malignant disease*, instead of being uncommon in the negro, is as often encountered in him in Southern hospitals as it is in the whites

Of 1620 deaths from malignant disease reported to the Louisville health office, 1413 were whites and 207 colored, or about one-eighth of the total number; *the normal proportion of colored population to white* in Louisville is one to four, which indicates the mortality in the colored population to be 50 per cent of *what it is in the white for cancers in all situations* This I believe to be nearer the truth than the smaller hospital series indicates, as it deals with the entire population of the city, and is moreover nearly in accord with Billings' eleventh census statistics (death rate 53 93 to 100,000 living white inhabitants and 36 65 colored) Further, these represent deaths, and are not open to the objections clinical diagnoses may be

The discrepancy between the statistics of the hospital and health office are apparent and not real, for, while the hospital shows the colored race to suffer as often as the white, it should be remembered that the improvidence and indigence of this race force them into the city hospital twice as frequently as the more favored whites The normal hospital proportion of colored to white is just double that shown by the city at large, hence the two reports are in perfect harmony and show the negro to suffer one-half as often from cancers in general as the whites

Mammary gland —Far from being uncommon, as *many practitioners believe, malignant disease of the* mammary gland is as frequent in the black as the white Personally, I have seen five cases, and know from a colleague that two others were recently in the city hospital The first case of cancer of the breast I ever saw was in a negress about forty years of age as black as a crow's wing She died from recurrence after operation, at the usual time and in the usual way, confirming the clinical diagnosis In all the others the clinical diagnosis was confirmed by the *microscope and by the death of each from recurrence*

There were 889 cases of cancer of the breast reported in the eleventh census, 811 females, 2 males One occurred under 15 years of age, 16 between 15 and 45, 670 at and over 45 Rate of death to 100,000 inhabitants females, 8 23, males 0 29, age 45 to 65, 30 08, 65 and over, 50 Death rate practically same in white (4 27) and colored (4 19)

The records of the Louisville city hospital for the past twenty years show that three-fifths of the cases were whites *and two-fifths colored, though the latter* represent but one-third of the hospital population Our health office shows that there were fifty-eight deaths from mammary cancer in the past thirty years Of this number fifty were white and eight colored

1868 to 1878—total number cases mammary cancer 14 white 14 colored 0
1878 to 1888—total number cases mammary cancer 17, white 15 colored 2
1888 to 1898—total number cases mammary cancer 27, white 21, colored 6

1868 to 1898 . . . . 58 white 50 colored 8

Undoubtedly there have been a larger number of deaths from cancer of the breast, but many have doubtless been entered as "cancer" without giving situation Small as this series is, it emphasizes the increase of cancer in the negro, especially, and shows that as a race they suffered more frequently than the white during the past ten years

Cancer of uterus — The eleventh census shows cancer of the uterus to be far more common in the colored race There were 1472 cases reported and the death rate was 24 94 in the negro and 14 41, or but little more than half the number in white women Table shows death rate per 100,000 during census period at all ages

	All ages	15 to 45 years	45 to 65 years	65 years and over
Total	14 93	9 32	54 01	45 91
White	14 41	8 79	52 29	44 36
Native born	10 98	7 51	51 71	43 71
Foreign born	22 92	11 98	50 79	41 77
Colored	24 94	18 82	94 59	88 36

The death rate is very much higher in the colored race for all ages

Both the Louisville city hospital and health office statistics show cancer of the uterus to be more common in the black race From 1878 to 1898 there were 31 cases of cancer of the uterus in the city hospital, of these 23 were white and 8 colored (normal proportion of colored to white in hospital 1 to 3), showing relatively a greater number of cases in the black race

1878 to 1888—total cases 13, white 12, colored 1
1888 to 1898—total cases 18, white 11, colored 7
1878 to 1898—total cases 31, white 23, colored 8

From 1868 to 1898 there were 272 deaths from cancer of the uterus reported to the health office of Louisville, of this number 216 were white and 56 colored It shows a per cent against the negro—our normal population being 1 to 4 Total number deaths from carcinoma uteri in Louisville from

1868 to 1898—272, white 216, colored 56
1868 to 1878— 39, white 29, colored 10
1878 to 1888—190, white 74, colored 27
1888 to 1898—133, white 113, colored 20

I would be glad to pursue the subject of regional liability in the two races further, but it is impossible at this time, suffice it to say that liable as the mammary gland and uterus of the negro are to malignant disease, certain other regions which one would expect to suffer often do so infrequently I have never seen cancer of the penis, larynx or tongue in a negro, while rectal cancers are common

Cancer is rare in Indians, and when it does occur, so I am informed, attacks the breast and uterus Great smokers as they are, their immunity to cancer of the lips has been remarked upon by a number of army surgeons who have written me Cancer is rare in all savage races, and is pre eminently an affection which increases in frequency with a higher state of civilization Dark-skinned races suffer less than the fair

Age and sex —Women are twice as liable to malignant tumors on account of their proneness to disease of the uterus and mammary gland, which embrace one-half of the cases in the female sex Snow's statistics, gathered from the Cancer Hospital in London, and those of W Roger Williams recently published, clearly attest woman's double liability The sexes are upon a parity up to the fifth quinquinnium, when the difference between them becomes striking From 25 to 55 the female is nearly three times as liable to malignant disease, and from 55 to 90 is almost twice as obnoxious Gusserow, who analyzed 3385 cases of uterine cancer, found only two to have occurred prior to 20, while of Gross' series of 1622 mammary cancers the youngest was 21, a ready explanation of the heavy tribute woman pays to malignant disease during the activity and devolution of her sexual organs

Age—Infancy and childhood are practically exempt from epithelial malignant neoplasms (cancer), the youngest case on record being one of cylindroma of the rectum in a girl aged 11 (Stern) Cancer being rare prior to 30, then gets to be more common, is ever thereafter more liable to occur with each succeeding year, and has been reported by Sutton at 102 Practically all tumors of infancy and early childhood are sarcomata, they being nearly as exempt from benign neoplasms as they are to true cancers Sarcomas of the eye, kidney, testis and prostate are common in infancy, and may be in many instances congenital

Duzan analyzed 182 cases of sarcoma in infancy, and found 70 of the eye, 45 of the kidney, 11 of the testicle, 8 of the prostate, while the bones, tongue, abdomen and brain were affected 5 times each, lung and dura mater 4 times, pancreas 3, liver, tonsil and rectum 2 each and stomach 1

During the second decennium the long bones and maxillæ are the usual sites of sarcoma The long bones still suffer in the third, and in the fourth decennium some of the long bones, as the humerus, and the mammary gland and testicle exhibit their greatest tendency to sarcomatous change After forty, sarcoma is rather uncommon until sixty, when it again becomes frequent Like cancer, it is common as a senescent change, but unlike it, shows its greatest destructiveness in infancy and early childhood

The following tables are by W Roger Williams, on "The Malignant Tumors of Infancy, Childhood and Youth," the *Lancet*, London, May 1, 1898

TABLE 1 Showing the deaths due to malignant disease at different age periods

Sex	All ages	Under 1 year	1-2	2-3	3-4	4-5	Total under 5 years
Males	57,454	8	6	6	6	5	31
Females	10 489	7	6	6	6	6	31

	5-10	10-15	15-20	20-25	25-35	35-45	45-55	55-65	65-75	75-85
Males	18	18	33	50	145	426	1095	1727	1555	591
Females	15	18	25	41	321	1313	2464	2922	2330	910

Over 85, males, 65, females, 101 Total both sexes, 16,243

TABLE 2 Showing the number of deaths from malignant disease in early life per million persons living at each age period

Age periods	Under 5	5-10	10-15	15-20	20-25	All ages,
1861-70	13	7	7	7	17	384
1871-80	12	7	7	15	27	464
1881-90	20	10	11	20	35	539

BENIGN NEOPLASMS

As a class the mesoblastic benign neoplasms are more common with the negro, he being exceptionally obnoxious to fibroma, lipoma and keloid Molluscum fibrosum, which I am not disposed to question is more frequent in the negro, is, I am sure, a more common affection in the whites of this and even more Northern latitudes than authorities admit Many speak of it as an affection almost peculiar to the black races of the tropics, yet I have in my own practice seen three most beautiful instances of this disease in white males, all past forty, within the last four months I have seen the disease more often in the white than the black Keloid is also, I take it, more common in the white race than many believe, though it is certainly many times less frequent than in the negro I have seen a number of typical keloids supervening upon vaccination scars, on the lobule of the ear after the piercing, and upon cicatrices variously situated, in the white race I agree perfectly with Tiffany that operation does no good in young subjects, and that there is in elderly persons afflicted with keloid a spontaneous tendency to undergo resolution There is no disproportion between the sexes in their liability to benign tumors

Age As has been intimated, the very young are practically exempt from benign neoplasms The first decennium suffers rarely, and then usually from congenital angeiomata and lymphangeiomata

TUBERCULOSIS OF BONES, JOINTS, SEROUS MEMBRANES AND GLANDS

Pulmonary consumption, which was practically ated upon by Louisville surgeons but one was in the negro I have at great pains seen every surgeon in this city and gone over their series carefully with them, and am sure that these statistics are absolutely trustworthy I have done more, and have gone to Dr Soloman, Curator of the City Hospital, who has kept a record of every postmortem examination he has made since he has been curator (two years) and in not a single instance have stones been found in the gall-bladder of a negro It, of course, was examined in every postmortem He found them frequently in whites

That the negro should suffer less frequently is, I think, explained by their more active life, better teeth and stronger digestion, coupled with the fact that they do not indulge in the highly seasoned and bilious-making food of the whites, they are also less liable to malaria and other conditions dependent upon, or associated with, a torpid liver

ANEURYSM

According to the Eleventh Census Report aneurysm is far more common (3 to 1) in the colored than in the white race The records of the health office in Louisville agree fully with Billings' statistics, showing that in a population of one to four there were nearly as many deaths in negroes as in whites (14 colored and 18 whites) in the last decennial period

Of patients treated at the Louisville City Hospital for ten years past, there were slightly more than three times as many negroes as whites, although the proportion of white to colored patients in this institution has been nearly three to one Sex also has a most marked influence in the etiology of aneurysm Crisp, in an analysis of 551 cases, found it to be seven times more common in men Souchon's series of 98 cases shows 76 males and 22 females An analysis of the cases at the Louisville City Hospital, and those reported to the health office for the past ten years, shows more than three times as many cases in men The disproportion in the two sexes is, I think, readily explained by the greater tendency of the male sex to arterial degenerations on the one hand, and their occupation and habits on the other Age has a most direct bearing, as aneurysm rarely occurs before 30 In the series analyzed by me none occurred under 25, there were but three under 30, aged 25, 28 and 28 respectively The greatest number of cases will be found between 35 and 55 The disease is rare after 60 The following table gives a record of all cases reported to the Health Department of the city of Louisville during the past ten years

	White		Sex not stated	Colored		Sex not stated	
Age	M	F		M	F		Totals
1 to 10							
10 to 20							
20 to 30	2				1	1	4
30 to 40	3		2	1	1		7
40 to 50	3		1	3	2	1	10
50 to 60	3	2			1	1	7
60 to 70		2		4		1	4
70 to 80							
Totals	11	4	3	5	5	4	32

Males White, 11, colored, 5, total 16 Females White, 4, colored, 5, total, 9 Sex not stated White, 3, colored, 4, total, 7

Aneurysm is apparently far more common in some races than in others, being very frequent and seemingly increasing in England, while it is one of the rarest affections in China, due, it is said, to the non-stimulating *rice diet, temperate habits, and phleg*matic temperament of the Chinese Prof Hunter McGuire, of Richmond, Va, writes me as follows "Aneurysm is much more common in the negro than in the white in my experience" Prof Tiffany of Baltimore writes of the frequency with which aneurysm occurs in the black race Nearly all surgeons to whom I have written and from whom I have received replies have remarked upon the greater liability of the black race to aneurysms I regret to say that few have given any reports of cases, and that these statements are merely impressions gained from a large experience but not substantiated by statistical detail It is certainly my own conviction that aneurysm is relatively far more common in the negro, and there fore, can not agree with Matas' statement that aneurysms are somewhat less common in the African, a fact he thinks due to their comparative immunity to gout, rheumatism and alcoholism

TETANUS

While tetanus is co-extensive with civilization, affecting every race and clime, it is more common in subjects living in hot climates and possessed of dark skins Negroes, Hindoos, South Sea Islanders, Italians, Spanish and French are less resistant to the germ of Nicolaier In this country the negro is unquestionably more obnoxious, the infant mortality being heaviest Appreciating the indifference with which negroes treat minor injuries, and their proverbial uncleanliness, we can well understand their greater liability to infection

The mortality among colored infants is particularly high in comparison to the white, which is explained by racial predisposition on the one hand, perhaps; and by the greater chance for infection through the cord of the newborn, cut as it is with dirty scissors, handled with dirtier hands and wrapped in unclean rags A large per cent of colored infants die from trismus neonatorum on Southern plantations, death usually occurring within a fortnight after birth In the Island of Jamaica and other more Southern countries, the death rate is at times frightful, being from one-quarter to one-half of all infants born, yet the whites here do not suffer to any degree

According to Billings' recent Census Report, there were 2019 deaths in the census year 1238 males and 781 females In 1880 the death rate was greater Persons from 5 to 15 years show the highest death rate (1 74), those from 15 to 45, 1 04, and over 45, 1 42 The death rate in boys was nearly five times as heavy as in girls There were sixty deaths in Chicago during the month of July, 1881, due to toy pistol accidents This, I think, explains the greater prevalence in males, they are simply more exposed to accidents of all kinds and are not more liable, *per se,* to infection

Tetanus is, or has been in past wars, frequently encountered in military surgery English soldiers in Spain suffered from tetanus in proportion to one case in eighty wounds, and in the East Indies, in 1872, twice as often During the civil war our troops were more fortunate A letter just received from Surgeon Major J C Merrill, United States Army, and librarian of the Surgeon-General's Office, is as follows "I would state that out of 246,712 injuries by weapons of war, 505 (0 20 per cent, or a little over two in a thousand) were followed by tetanus I may add that over one-half of these cases occurred after injuries to the *lower extremities, a fact that has been noted* by several authors in other statistics Your second question, as to the relative frequency of tetanus or erysipe las in colored and white troops, and also in North American Indians, can not, I think, be answered without an amount of search that would require weeks to make it valuable Isolated cases are reported here and there, but I know of no statistics of sufficient numbers to throw any light on this matter "

The Italians, Spanish and French have suffered more in their wars than soldiers of more Northern countries with fairer skins Sudden variations in temperature and the depressing effects of defeat, have always increased the number of cases in military surgery

I am told by Hebrew surgeons that trismus neonatorum is more common than it should be in Jewish infants It can well be explained, if true, by the manner of performing the ritual circumcision The Mohel is necessarily surgically unclean and careless in performing the operation, and infection should be easier than if this function were transferred to surgical hands I am reliably informed by one of my Hebrew medical friends of Louisville that a well-known Mohel of that city is himself infected in a serious way, and a very unfit person to officiate as he does I am further told by Jews who were born in Russia and other countries, that an affection, which I take it from their description, must have been trismus, is quite common among Jewish infants there The Jews are a shrewd, wideawake, sensible people, quick to see their own interests, and it is reasonable to assume that time will soon bring about a change of sentiment in this rite

Health office —Deaths reported due to tetanus from 1888 to 1898

White 5, colored 3, total, 8 cases age not given, white 39, colored 16, total 55 cases over one month, white 126, colored 29 total 155 cases under one month Total, 218 cases Total white, 170 Total colored, 48

VARICOSE VEINS

Varices of the limbs are but seldom encountered in negroes Of 23 cases of varicose veins of the legs, without ulcer, there was but a single case in a negro, a male aged 44 Of 29 varicose ulcers there was only one case in a negro, a man aged 53 Of the 45 cases there were 13 females and 32 males

Varicose veins of the limbs are rare before 30, there being but two in the series, aged 27 and 28 respectively Between 30 and 40 there were 4 cases, between 40 and 50 there were 4 cases, between 50 and 60 there were 6 cases, between 60 and 70 there were 7 cases, between 70 and 80 there were 2 cases Varicose veins of the limbs are uncommon with Indians, Mexicans and Chinese

ERYSIPELAS

The total number of deaths due to erysipelas, in the United States Census Report just issued, was 2663 The death rate per 100,000 inhabitants was as follows Under 5 years 31 34, 5 to 15 years 0 81, 15 to 45 years 2 80, 45 to 65 years 8 88, 65 and over 38 55 Very few cases occurred in colored persons, so few as to be of no value A careful examination of the records of our city hospital and the Louisville Health Office shows that the disease is not so rare in the negro as many suppose Of 79 deaths due to erysipelas, reported in the past ten years to the health department of this city, 17 were colored, which is about the normal proportion, our population being one to four

Those who are unaccustomed to seeing erysipelas in the negro are apt to overlook it on account of the color of his skin Sex would seem to have but little effect The two extremes of life suffer by far most frequently, young adults and middle aged persons having it but rarely Erysipelas of the newborn has not been a frequent affection in Louisville, judging from records of deaths reported to the health department In ten years there have been 11 cases dying within the first month of life, of these 10 were white

STONE IN THE BLADDER

Dr George Ben Johnston of Richmond, Va, has made a careful investigation of 1068 cases of urinary calculi occurring in twelve Southern States, and finds that the negro is less immune to this affection than has been hitherto believed by many surgeons It occurs once in every 11,732 whites, and in the black race once in 55,305 It is, then, nearly five times (4 72) more frequent in the Caucasian Sex was specified in 708 cases, there being 691 in males and 97 in females, more than seven times as frequent in the male sex The ages of his cases in this large and interesting series were not given, I regret to say Gross analyzed 6042 cases of urinary calculi with reference to age, and found that

2334 occurred from 1st to 10th year
1079 occurred from 10th to 20th year
513 occurred from 20th to 30th year
353 occurred from 30th to 40th year
422 occurred from 40th to 50th year
536 occurred from 50th to 60th year
587 occurred from 60th to 70th year
201 occurred from 70th to 80th year
17 occurred from 80th to 90th year

It will be seen that more than one half of all cases occurred within the first two decades of life, and that the first furnishes more than double as many cases as the second, the latter more than double the number in the third decade The ratio is then pretty well maintained until the sixth decade, when an increase is noted, this increase to be still further augmented in the seventh decade When it is remembered that there are relatively fewer persons living in the sixth and seventh decades, it will at once be seen that the two extremes of life, the first and seventh decades respectively, are most obnoxious to urinary calculi Stone in the bladder occurs everywhere, affecting every race, but it is found in some countries more frequently than in others In North America it is found most frequently in Kentucky, Tennessee, Ohio, Missouri, North and South Carolina, Virginia and Georgia New England is relatively exempt, as are also Mississippi, Alabama, Arkansas, Louisiana and a few other Southern States Stone is common in France, Austria, Hungary and Russia, seldom seen in Spain and Switzerland It is also frequent in England, though less so in Ireland It is very common in India In China gravel and calculus are, according to Gudgeon of Pekin, among the rarest of affections Stones are common enough at Canton, but of infrequent occurrence at other points It has been supposed to be due to the fact that the inhabitants here live largely upon fish, but this can hardly be, as Gudgeon states that the diet, water and habits are the same here as at other Chinese centers

Opium eating is supposed to lessen the liability of the Chinese, as a race, to stone Certainly it is not the drinking of limestone water, as river water is universally drunk and very generally boiled before drinking Little cold water is drunk in China A number of my surgical friends in the Medical Corps of the

United States Army assure me that stones in the bladder and kidney are rare among the North American Indians, and the reported cases will generally be found to have occurred as a result of traumatism, a nucleus in the bladder inviting the deposition of the solid constituents of the urine around it. I have reports which justify me in thinking that vesical calculi are more common with Mexicans, one operator in the small town of Santa Fe reporting five operative cases.

STONE IN THE KIDNEY

Practically all that has been said of vesical calculus pertains with equal force to the renal variety. The two extremes of life are most obnoxious, males also suffer about twice as often as females, some placing it as much as three times as frequently. Some excellent authorities, however, as Duplay, Reclus and others, think the two sexes equally affected. It is very certain that the disproportion which exists between the two sexes in vesical calculus does not exist here, and does occur in the former disease for obvious anatomic reasons. The short, capacious urethra of the female easily allows gravel to pass, which in the male must remain in the bladder and act as nuclei for future stones. No cases have been reported to me as occurring in the negro.

OVARIAN GROWTHS

Ovarian tumors, cystic and solid, occur at all ages and in every race so far as I know. The more usual form of growth is cystic in character, simple or dermoid. Both varieties may be congenital, frequently are, and only await the stimulation which puberty brings to awaken them into renewed life. Therefore, while the records abound with instances of operations done upon simple and dermoid cysts in children by operators all over the world, we may say that prior to puberty ovarian growths are relatively rare. An infant four months old was successfully operated upon by D'Arcy Powers at the Victoria Hospital for an ovarian cyst containing fifty-nine ounces of fluid, reported only a few weeks ago. Hoffman reports an unsuccessful case at three months, the tumor containing six to eight pints of fluid and the solid portion weighing 2½ pounds, in all 10 pounds. Busch operated unsuccessfully upon an ovarian cyst in a child 24 months old. de Santa Anna removed a dermoid cyst in a child 1 year old, and Roehmer one from a child 20 months old, and Schwartz one from a child 4 years old. Mears, Barker and Rein have operated in cases of children under 7 years of age, while Thornton, Lucas, Hamaker, Cupples and Chenoweth have operated in children from 7 to 7½ years. Sir Spencer Wells and many others report operations in children under 10 years of age.

As to the other extreme of life, the same may be said, the octogenarian being not immune. A great number of cases have been reported in women past 70, and a reasonable number 80 and beyond. Cartledge of Louisville, recently operated successfully upon a case past 81. Hoffman reports a case at 82. But, while it is true that ovarian cysts may and do present themselves at any age, it is also true that they are most likely to develop during the sexual life of the host. Puberty stimulates not a few to rapid growth, especially dermoids, therefore, it is not unusual to find such growths under 20. They, and all other ovarian tumors, are more common, however, during the next three decades of life.

Much has been written about the immunity of the negro to cystic diseases of the ovary, yet literature teems with instances of the affection in the colored race. It is unquestionably less common in the negro, but the difference in liability of the two races which is supposed to exist by many surgeons is not supported by careful statistical data. A great many ovarian cysts in the negro, full-blooded as well as mulattoes, have been reported to me by various surgeons of the South. The records of the Health Office of the city of Louisville show that there have been nearly one-third as many deaths from ovarian tumors in the colored race as in the white during the past ten years. This would indicate them to be even more common than in the white, as the normal proportion of colored to white population is one to four, yet this is not the case, I fancy, as the discrepancy is easily explained, I think, in several ways. In the first place the colored race is less resistant to surgery of all kinds, which fact seems clearly established by Matas, from the enormous experience of the Charity Hospital of New Orleans. In the second place negroes are oftentimes operated upon by less skilled abdominal surgeons and under environments less advantageous than whites enjoy.

I am, to conclude, satisfied that the supposed immunity which the negro is thought by many to enjoy does not exist, except to a limited degree, if at all, for if they were immune at one time, the immunity hitherto enjoyed, has, like unto that from malaria and yellow fever, almost wholly disappeared. The size of ovarian growths varies from a walnut to a mass aggregating a weight of 245 pounds, the largest tumor on record, removed by Cartledge of Louisville, within the year. A female laparotomist of Japan removed one weighing considerably less. Keen of Philadelphia, removed a very large tumor in a girl 15 years of age, weighing 111 pounds, the child weighing, after removal, 68 pounds.

Malignant disease (usually sarcoma) of the ovary may occur. It is four times as common before the age of 15 as afterward, 25 per cent die from any operative interference, and nearly all within a year from recurrence. Convalescence is also tedious in those who survive operation.

CONGENITAL DEFORMITIES

Harelip, cleft palate, clubfoot, spina bifida and all congenital deformities are certainly less frequent in the negro, judging from the experience of Louisville surgeons and other practitioners in Southern cities to whom I have written. But a single case of harelip and cleft palate, both in the same individual, has been operated upon in Louisville, so far as I can learn from personal interviews with its surgeons and examination of the records of the city hospital and college clinics, for the past ten years. Clubfoot and spina bifida in the negro have never been encountered in my practice, nor so far as I can learn in the practice of other Louisville surgeons. Dr Vance is positive that he never saw a case.

Congenital deformities of all kinds are also reported to be most rare with Indians. The only deformity reported by any of the many army surgeons to whom I have written was one case of clubfoot and a double harelip, both in Sioux children. The clubfoot was in a boy and the sex of the harelip case was not given by the reporter, Dr William L Kneedler, captain and assistant surgeon, United States Army. Other army surgeons who have answered my inquiries have all stated that they have never met with these deformities in Indians, most of them, however, stating that they may not be so rare as their observations would indicate, for it is the custom of the Indians to put deformed children to death soon after birth The Jews, I am informed, suffer less than others from congenital deformities The Mexicans as a race suffer more frequently than Indians from all congenital deformities, and a number of cases of harelip, clubfoot, supernumerary digits, etc , have been reported to me One family in the practice of Dr J M Diaz of Santa Fé, N M , is remarkable for each of six children having six fingers and as many toes upon each hand and foot

APPENDICITIS

That appendicitis is relatively a rare disease with negroes is a fact substantiated by all Louisville surgeons and others from whom I have received answers to my questions In an analysis of 250 cases operated upon by Louisville surgeons, but 5 cases have been reported in negroes This would indicate a striking immunity, as it shows the disease to be only one-tenth as common in the black race

Sex —Nearly all writers on this subject have remarked upon and tried to explain the greater frequency of appendicitis in the female That it is more common in men none will deny Just what the difference in liability is, it is not easy to say Fowler's statistics indicate it to be rather more than four times as common—142 men, 35 women In 92 cases analyzed by myself there were 58 males and 34 females

Age —The influence of age is not less marked than that of sex and race The disease is common between 15 and 35 Though Hold, Villard and others report cases under 5 years of age, but few are of record, and we are justified in saying that the first quinquinnium of life enjoys a practical exemption from this affection It is rare in the second quinquinnium, more common in the third, liability further increased in the fourth, and reaching the maximum in the fifth quinquinnial period, then declining slowly in the sixth, seventh and eighth to become thereafter a rare disease The average age in 92 cases was 23 13 years

I have analyzed 92 cases with reference to age and sex Of these there were 58 males and 34 females The ages were as follows

	Cases
Under 5 years (3¾ years)	1
5 to 10 "	9
10 to 15 "	11
15 to 20 "	18
20 to 25 "	19
25 to 30 "	16
30 to 35 "	4
35 to 40 "	4
40 to 45 "	5
45 to 50 "	2
50 to 55 " (51, 52 and 53)	3
Total	92
Average age	23 12 years

In Fowler s 169 cases (*Annals of Surgery*, May, 1894) 142 were males and 35 females The age of the youngest was 2 5 years, the oldest 68 years In the youngest case the disease was tubercular in character This was the only case occurring under 5 years of age

	Cases
Between 5 and 10 years	8
" 10 " 15 "	21
" 15 " 20 "	29
Between 20 and 25 years	43
" 25 " 30 "	23
" 30 " 40 "	28
Over 40 years	16

Experience of Louisville surgeons

James M Holloway—"I recall but one case in the negro " Ap Morgan Vance—"Forty-four cases, one negro, average age 24 " A Morgan Cartledge—"I have operated but once on the negro in more than one hundred cases first, second, third decade " J Garland Sherrill—"Three cases, none in negro aged 55, 20 and 38 " H Horace Grant—"About 5 per cent in negro " W O Roberts—"About twenty cases, one in negro " T B Greenley, Meadow Lawn, Ky —"Have never seen case in negro " J R Buist, Nashville, Tenn —"Common from 5 to 40, rare in negroes " Hunter Maguire, Richmond, Va —"I see very little difference in appendicitis in the two races, probably it is a little more common in my experience in the white " L McLane Tiffany, Baltimore, Md —"I have operated upon two negroes for appendicitis, one a male child, one a young male adult " In more than fifty operative cases I have seen appendicitis but once in the negro

RECTAL DISEASES

That all periods of life do not suffer from the several diseases of the rectum is apparent to every observant practitioner Children frequently have prolapsus ani and polypi, but rarely other rectal affections Elderly persons also enjoy a relative immunity to rectal disorders, as they suffer infrequently from the more common troubles, hemorrhoids and fistula Cancer, to be sure, is more frequent with them, but it is, comparatively speaking, a rare disease Middle life is the time when piles, ischiorectal abscesses, fistulæ and fissures are most prone to occur They are all frequent An analysis of 70 cases of hemorrhoids shows only three patients under 20 to have suffered—at the ages of 14, 18 and 19 years respectively

Suffered in the third decennium,	14
Suffered in the fourth decennium	15
Suffered in the fifth decennium	19
Suffered in the sixth decennium	19
Suffered in the seventh decennium	3
Total	70

Sex seems to have an influence, as less than one-third were females (females 23, males 47)

Race has a more marked influence, there having been 60 whites to ten colored As these were hospital cases where the proportion of colored to white patients was 1 to 3, piles seem to be more than twice as common in the white

Hemorrhoids are said by army surgeons and others to be rare among the North American Indians The celebrated authority, Van Buren, who spent some years among them, stated that he never saw a case of piles in an Indian Dr F A Winter, assistant-surgeon, United States Army, informs me that hemorrhoids are reported to be common with the Mexicans, and their liability is supposed to be due to the free use of mescal Piles are common with the Mexicans of New Mexico where pulque is not used as a beverage, and is supposed by nearly all of the practitioners of the Territory, to be due to the free eating of Cayenne pepper

I am told by careful observers doing much practice among the Jews that they are as a race, liable to rectal affections Dr Gerster of New York, for many years surgeon to Mt Sinai Hospital where the patients are mostly Hebrews, gave it as his opinion in a paper read before the American Surgical Association, that this race frequently suffered from rectal affections He expressed the same opinion to me personally

Fistula in ano is just as common, or nearly so, in the colored race as in the white An anaylsis of 43 hospital cases shows 33 in whites, 10 in negroes, normal proportion of colored to white, nearly 1 to 3 The liability of the negro to tuberculosis explains his being more frequently affected with fistula than piles Twenty-seven of the series were males and 16 females

Age—The first decade, as in piles, furnishes no cases, the second but 5 cases, aged 13, 16, 17, 18 and 19 respectively

	Cases
The third decennium furnishes	12
The fourth decennium furnishes	10
The fifth decennium furnishes	4
The sixth decennium furnishes	11
The seventh decennium furnishes	2

Fistula is undoubtedly more fatal in the colored race Of the fatal cases reported to the Louisville Health Office during the past ten years, there were nearly twice as many deaths in negroes, although the normal proportion of colored to white population is only 1 to 4 This would indicate fistula in the negro to be nearly eight times as fatal as in the white The excessive mortality in the colored race can be explained by their greater tendency to tuberculosis, sepsis and syphilis

ACUTE INTESTINAL OBSTRUCTION

Omitting congenital malformations as a cause of obstruction, we have first, invagination or intussusception, second, impaction of foreign bodies, notably gall-stones, third, volvulus or twisting of the bowel upon its axis, said to be due to elongation of the mesenteric attachment of the gut, and fourth, internal strangulation either due to an inflammatory band, a Meckel's diverticulum, or a protrusion of the gut through some internal opening I have only chosen to consider acute obstruction, as it would seem to have a more direct bearing upon the questions of age, sex and race

Intussusception—Intussusception causes at least one third of all cases of acute intestinal obstruction According to W Brinton, who analyzed 12,000 postmortem examinations, insussusception causes about 43 per cent of all cases Leichtenstern and Fitz place the figures at 38 per cent, others place them as low as 30 Intussusception is *pre-eminently* an affection of *infancy* and *early childhood* L Emmett Holt has collected 385 cases of intussusception in young children, 141 were under six months old, 89 between six and twelve months, 32 between the first and second year, 96 between two and ten years It will be seen that considerably more than one-half of these cases occurred within the first year It was encountered more frequently in males than in females—174 against 94 In adults intussusception is said to be more common in women than in men (Park's "System of Surgery") At least one-half of all cases of intussusception take place at the ileo cecal junction Of the remaining cases twice as many will occur in the small intestine as in the colon

Impaction of foreign bodies — Foreign bodies, hardened feces, and especially gall-stones, may occasionally cause intestinal obstruction From statistics, which I have carefully examined, it would seem that this will explain about one case in fifteen of intestinal obstruction I have seen two cases caused by impaction of enormous gall-stones, both in elderly subjects (white) and in females Occasionally an instance will be met with in a child who has swallowed foreign bodies Cases due to fecal impaction are usually in elderly subjects, a decided preponderance being females

Volvulus—Intestinal obstruction due to volvulus is comparatively rare It nearly always occurs after middle life, frequently in elderly people, and is three to four times as common in men as in women Elongation of the mesentery, which is supposed to act as a cause, may be congenital, but is usually exaggerated late in life as a result of prolonged traction, therefore explaining the relative frequency of this affection in elderly subjects, just as hernia is accounted for in the same way

Internal strangulation—This variety of intestinal obstruction is the most frequent of all It may be caused by a Meckel's diverticulum, inflammatory bands, retroperitoneal herniæ, prolapse of the intestine into an abnormal pouch, or be a form of hernia An intussusception is closely identified with the first decennial period of life, and volvulus with elderly subjects, this variety is associated with those between the two extremes of life This is, as we might expect, on account of occupation, exposure and the diseases to which we are liable during the active period of existence In men it may follow appendicitis caused by a band constricting the bowel, in women it not infrequently follows pelvic inflammation

Race—Of 45 fatal cases of intestinal obstruction reported to the health office for the past ten years, 40 were white and 5 colored, 26 males, 19 females This would indicate a mortality in the white race exactly double what it is in the black (Normal population one to four)

White, male 23, female 17, color not stated 10, colored, male 3, female 2, sex not stated 1, total 56

CHAIRMAN'S ADDRESS

[ABSTRACT]

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10, 1898

BY JOSEPH PRICE, M D
PHILADELPHIA, PA

In the early history of gynecology the real pioneers had not only the scientific knowledge to attain, but principles to practically apply, means and methods to adopt without the aid of precedents or the counsel of fellow practitioners It has always been difficult to perfect and establish a procedure

McDowell operated with a mob at his door Nineteen and ten years before McDowell's operation, William Bainham did two successful operations for ectopic pregnancy Doubtless the success of Bainham's operation greatly influenced McDowell and was inspiration in his own heroic and successful work Yet notwithstanding this success there was a suspension of the operation for a quarter of a century Not again was the operation resorted to until 1843 Then by John Light Atlee of Lancaster, Pa , and John Clay of Manchester, England To the extent to which these pioneers carried their work, we have in our own work, without material change, followed their methods, ecting somewhat the lessons they taught and ırging the field of their application Ignorance prejudice yet face us at every turn, repeatedly osing from sources from which we have the least ıt or reason to expect it The old conflict is not altogether dead, buried and out of sight and ring Those whose courage was great, motives thy, were abused for throwing light into the kness in which the great body of the profession oped

'o illustrate and somewhat contrast the spirit of ı and now we let Dr Atlee speak "It is well wn that from the earliest period of ovariotomy in ladelphia down to the present time it has been my ıriable custom to invite members of the profession ıitness the operation, in order that they might be to form a proper opinion of its character and to ge of its propriety There was not a prominent lical gentlemen in this city that had not such an ortunity It was a rare circumstance during the bationary stage of the operation for any one to ept the invitation cordially and gratefully Some so coldly, as if conferring a favor upon me, others tely declined, others positively refused and emphatically condemned the operation, while others took the invitation as an insult" "Gentlemen who were bold enough to witness the operation were even directly accused by their professional acquaintances of being *particeps criminis* in committing murder, notwithstanding these murdered patients recovered Some high in the profession, against all ethical consideration, would call upon the patients who had finally decided upon the operation for the purpose of warning them against me and certain death The colleges proclaimed fiercely against the operation as unjustifiable and criminal" Professor Meigs thus emphatically expressed himself "I detest all abdominal surgery, I am free to say that I look upon all operations for the extirpation of the diseased ovary as not to be justified by the most fortunate issue in any ratio whatever of the cases, or in other words, not to be justified by any amount of success"

It is very good for men to be honest in their opinions, it is very much better for them, in spirit and in fact, to be right in them Oliver Wendell Holmes has aptly said "There can be no reason why the student of science should limit his attention to his specialty, though there is abundant reason why he should avoid any attempt to make researches over too wide a range of ground His researches in his own special corner of science will lose nothing in value, but gain greatly, by an occasional survey of the work of others, only let him not pretend to take part in actual work in many parts of the field he surveys" All troubles to which women are subject, medical and surgical, are found within the field of the general practitioner He should be a skillful diagnostician and should be competent to deal directly with many minor gynecologic troubles

In the last decade the younger school of gynecologists have unfortunately lost interest or neglected plastic surgery The great majority of them have been seized by the strange, inexplicable infatuation for the surgery of the peritoneal cavity

The vital questions relating to plastic work have largely dropped out of the discussions of our societies there are few recent contributions to our literature worthy careful study Along this line we are slow in following the footsteps of the older specialists, the compeers and followers of Sims Sims, followed by his pupils, gave his plastic operations, methods and instruments, as yet not improved upon by modification or otherwise All know the beautiful results following careful and successful work, and fully recognize that it is not work to be done by a mere apprentice to secure desired results The reports of vesico-vaginal fistulæ run about as follows "Two attempts at closure resulted in benefit to the patient, reducing the size of the fistula" Distressing conditions are not corrected, because gynecologists are not giving the subject the careful study its importance demands My own experience can not differ widely from that of many others In a recent series of cases I had four of vesico-vaginal fistula They were sent to me either by their friends or physician In each case there had been three or four attempts at closure, all failures These failures were explainable from the certain premises that the patients had not been thoroughly prepared for operation by the common methods so fully detailed by Sims and his pupils Operations for opening into the bladder, for complete laceration of the sphincter are failures in great numbers Some operators seem to miss the sphincter absolutely Careful training in plastic work is of more importance than in abdominal surgery An apprenticeship in a gynecologic dispensary gives a practical knowledge of skin diseases about the external genitals, of parasites and growths, and also lacerations, that is rarely obtainable in private practice Simple ovariotomies are easy, compared with the delicate, tedious and difficult work of dealing with mutilations where they are extensive, where we have lacerations of the urethra, perineum, bladder and cervix, or a very common distressing disorder, uterine displacement, which received prolonged and careful attention at the hands of the early and prominent gynecologists Of late years the preparation of the patient and soft parts for operative interference has not been sufficient Uterine displacements were treated successfully by simple methods by the early gynecologic specialists Hodge, Sims, Gaylard, Thomas, Albert Smith and many others of equal prominence at home and abroad, corrected the displacement or put the uterus in the normal or desired position with some form of properly adjusted pessary Displacements are quite generally shirked or neglected The very common office attempt at local treatment and the correction of displacement is an error and about always a failure Both office and the run-about treatment in the whole range of gynecologic disturbances are to be condemned Women with uterine posterior displacements should be put to bed, uterus put forward, all lacerations repaired and a well-fitting pessary placed Many general practitioners who make no pretense of special skill or knowledge, succeed beautifully in correcting displacements, this they do by putting the patient to bed and correcting the retroversion or the retroflection by using one of the varieties of the Albert Smith or Hodge pessaries, with Gayland Thomas modification The great, round, soft rubber rings are useless and harmful, but are in much too common use The stem girdle pessaries are of but little value All lacerations should be carefully repaired and posterior displacements carefully corrected before any of the usually adjusted pessaries are placed

The rest treatment for the correction of displacements is the shortest, surest and most satisfactory Anterior dressing of the uterus for a few days with the patient remaining at rest, in the Sims position, favors a very speedy recovery

It should not be taken that there are no risks associated with these mechanical appliances Early in the history of the use of the pessary there were numerous accidents I have removed them when very careful dissection was required, when the patient had worn them for ten or twelve years and had lost all knowledge of their presence I have found them deeply buried and the patient dying No great skill but great care is to be exercised in their application Men familiar with placing them get good results, and rarely have accidents The statistic records of accidents have a warning in them An eminent physician has published an analytic monograph in this relation and tabulates results as follows "Twenty-three cases of perforation of the rectum by the pessary, 20 cases of perforation of the bladder alone, 10 cases of perforation of the bladder and rectum, 1 case of ureteric fistula alone, 1 case of ureteric and vesico-vaginal fistula, 1 case of perforation of Douglas' pouch (neither fatal), 3 cases of perforation of the vaginal wall, the extruding portion of the pessary lying in the pelvic connective tissue, and 6 cases of the entry of a vaginal pessary into the uterus"

This record sounds a warning as to the importance of care in the application of the pessary There has been no very recent startling of the profession by the announcement that someone had invented a new pessary It is to be anticipated that during the meeting of our Association there will be a very lively shucking out of new methods of procedure

All we know of the physiology of uterine action compels us to regard the uterus and ovaries as the strongest links in the chain of woman's health of mind and body

Be not deterred by false sentiment or the jealousies of those who would rather keep their patients in their own hands than see them cured by others from doing what we know to be our duty

"Do we not all know by sad experience of the years of useless suffering that might have been spared, of lives that might have been saved, of the ruin of conjugal happiness that might have been averted, of material usefulness that might have been preserved had an accurate diagnosis been arrived at in the earlier stages of uterine disease and a proper line of treatment adopted

"In prolonged disorders of the uterus, resulting in enlargement, hyperplastic deposits or a process of fibroses following on arrested involution, in those secondary pathologic conditions attending upon lacerations of the cervix, in deep erosions, in unrelieved versions and flexions, in tubal enlargements and displacements, and in chronic affections of the ovary, as sequelæ of pregnancy, we find not only these reflex conditions present, but more aggravated pathologic consequences and more serious disturbance of function" These are the mature opinions of MacNaughton Jones and other eminent English specialists and general practitioners I strongly direct attention to this subject because it has not received the attention its importance deserves It has had a few able and courageous champions who have had to contend against obstructions raised chiefly by members of the profession from motives which we will not attempt to analyze

I am satisfied that many cases of nervous disorder could be averted or cured by early and careful attention to uterine and ovarian troubles and the examination of pelvic viscera We can only clear away doubts and establish safe scientific methods by utilizing the lessons of the observations and clinical experience of men who are working among facts

Our surgery is very much more than an art, it is also a science without limit, a science with no tolerance for obstructionists, no false deference for the venerable, that replaces the old with the better new We are not accepting mere opinions for truths, we are demanding scientific and practical tests, that old knowledge shall pass the crucial test of modern experiment and analyses We recognize that we have not reached the "last results," that there is enough we do not know to keep us from falling into a condition of inertia, to furnish us with extensive "happy hunting grounds" I could not refer to many of the evidences of our progress without raising controverted questions

We have given and continue to give names to things we do not understand, we know little or nothing about We have cancer, typhoid and puerperal fever, they are names for conditions, there we are estopped, finding ourselves face to face with the unexplained, we grope for the cause and remedy Among the best evidences of our progress are our medical journals They are largely to be credited with the scientific spirit, the earnestness of research diffused through the profession, they bring forward questions of direct and current interest, touch our every-day work, give those facts of our clinical experiences which constitute our best lessons, they index our progress Our periodical literature has largely taken the place of our old text books Our leading minds, where they have something to say, say it through our magazines, and give us the best they know To the busy physician the Journal is largely his literary world The Journal of the American Medical Association speaks for us as an Association, it is our official organ, it represents our scientific spirit and activities, the results of our study and research Through it the teachers in our colleges, the specialists and general practitioners speak However able and enterprising may be the editor, the Journal will not rise above the high water mark of the scientific intelligence of the American Medical Association—the great representative body of the American medical profession—by its report of our work we will be judged at home and abroad

In conclusion I can only make brief reference to obstetrics It is gratifying to know that the mortality in child-bed has been greatly reduced, this is largely due, both in lying-in institutions and in private practice, to cleanliness of environment In maternity cases it is in the great majority of instances dirt and meddlesome or unskillful instrumental interference that kills To have skillful obstetricians, the teaching of our schools should be more thorough, theoretically and practically Our students pay liberally for their advantages and should be dealt with liberally, every avenue to thoroughness should be open to them The professor who teaches him obstetrics should know the science and art of his subject and how to teach it As a rule the professor of obstetrics is not an enthusiast in his line, nor does he infuse interest and enthusiasm in the student, his teaching is largely perfunctory He teaches one subject, or professes to, while he practices another About all of them *want to be* gynecologists and specialists Some of them take to neurology, which requires great versitality of genius, the art to write poor poetry and indifferent fiction There are ample facilities in our educational centers for practical education in obstetrics hospitals, courts and alleys are open The student should be given that which will enable him, when he goes home, to go to work and do good work

ORIGINAL ARTICLES.

THE QUALIFICATIONS AND DUTIES OF THE MILITARY SURGEON

BY LIEUT-COL N SENN, U S V

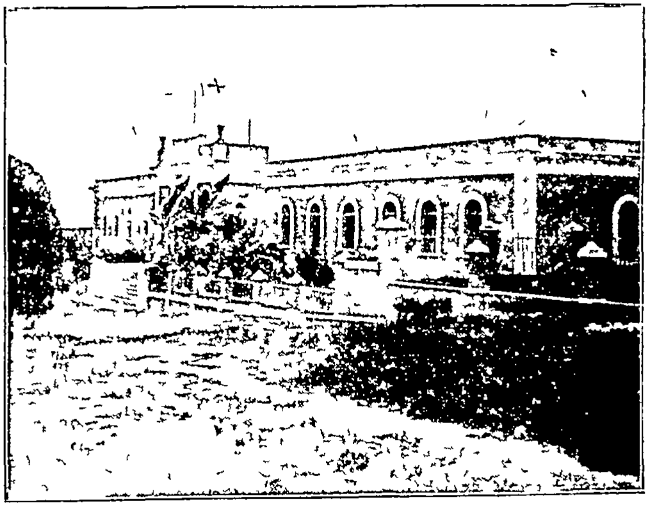
CHIEF OF OPERATING STAFF WITH THE ARMY IN THE FIELD

Nearly five months of continuous service with the army in the camp and field has afforded me an excellent opportunity to make a practical study of the above subject This time was spent in Camp Tanner, Springfield, Ill, Camp George H Thomas, Chickamauga, Ga, and the Cuban campaign, the time being about equally divided in the different places The first four weeks were occupied in Camp Tanner, where I assisted in the capacity of Surgeon-General of the State in the organization of the State troops This service brought me into closer contact with the National Guard of our State than at any time before A physical and professional examination in which I took part brought out the shady as well as the sunny side of their qualifications The result of my experience here convinced me that the average National Guard surgeon is a faithful doctor, with more than average professional ability, but, with few exceptions, lacking the necessary military training in performing satisfactorily his administrative duties This is a part of his education that has been sadly neglected in the past and should receive more attention in the future Very few States make provision for physical examination of the medical officers, consequently some of them have entered the service totally disqualified for participating in an active campaign Two of the candidates for the volunteer service from the National Guard of Illinois were rejected on this ground The four weeks' service at Camp George H Thomas as chief surgeon of the Sixth Army Corps opened up a wide field for extended observations in making comparisons between the work done by the surgeons of the regular army and of the National Guard The surgeons of the United States Army are all men of superior education, splendid physical development, and those who have been in the service for several years are well versed in the routine work of the Medical Department However, in all matters pertaining to medicine and surgery the average National Guard surgeon more than holds his own This superiority of the National Guard surgeon over his colleague of the regular army is no reflection on the latter, it is the natural outcome of circumstances, which made such a difference inevitable The young army surgeon has to spend many years at small and often out-of-the-way posts, where the opportunities for clinical experience and intercourse with professional colleagues are necessarily limited He naturally soon falls into the monotonous and routine work of the post life, with little or no inducements to continue his post-graduate scientific and medical studies When the time comes to pass an examination he wakes up from his lethargy sufficiently to go through the different compends to prepare himself for the coming ordeal He breathes easy after he has reached the major's rank, as this promotion forever closes the door of the much-dreaded green room From now on he is in the line of slow promotion without any extra exertions on his part He receives his salary and looks confidently for assignments to posts where he can spend the balance of his life in ease and luxury He has reached a time in life when he feels that he can avail himself of the work of his subordinates without interfering with his emoluments or his position in social and military life He is conscious of the fact that he has reached a rank and a station in life where it is proper for him to look to his assistants to do the drudgery which he had become accustomed to in the past, and begin to enjoy the life before him It is different with the military surgeon taken from civil life He emerges from the turmoils of family practice From the day of his graduation he has tasted the bitter fruit of active competition His work has been watched with an envious eye and subjected to sharp criticism by his neighboring colleagues, old and young He felt from the very beginning of his professional career that success depended upon his own exertions The average American practitioner is a hustler He is willing to work night and day to gain a lucrative practice and the social position which goes with it With few exceptions he knows that what he has learned in college is but the entering wedge to a comprehensive knowledge of the practice of medicine and surgery He knows that our profession has become a progressive one His college education tells him what is new today will be old tomorrow He looks with pity on his colleagues, advanced in years whose language and practice convince him that they have fallen into a dangerous rut He reads the numerous medical journals, the great avenues of recent medical literature He spends his scanty income in purchasing new books and instruments for scientific investigations All requisitions are made on himself and are honored only by writing his own checks He joins medical societies, large and small, and attends their meetings regularly He listens intently to the reading of papers and discussions to increase his store of knowledge and returns to his limited field of action better prepared to battle against disease He mingles freely with the members of his profession, always ready to absorb and digest new ideas He makes frequent pilgrimages to his alma mater or some post graduate school to familiarize himself with the most recent advances in medicine and surgery Social life has no attractions for him he has entered the profession for the sole purpose of becoming an influential and successful practitioner This is the kind of material our National Guard surgeon is made of No wonder he outweighs the professional military surgeon in practical knowledge required in the treatment of injuries and disease

The exacting and often onerous duties of the military surgeon in times of war require special qualifications to prepare and fit him for his work He is not only expected to be well versed in theoretical and practical knowledge of everything pertaining to the practice of medicine and surgery, but he must be endowed with qualities both of mind and body upon which he can rely when engaged under the most trying circumstances In field work he has often to perform the most difficult tasks ry resources In such instances good common sense and deliberate action go much further in accomplishing what is desired than the finest scholarship and the most profound logical reasoning The man who can in a few moments extemporize a well-fitting splint out of the simplest materials and perform with the contents of an ordinary pocket case the most difficult operation will do vastly better work on the battlefield than most professors of surgery and the most brilliant operators in civil practice The surgeon who understands the principles and practice of good cooking is of more service to the troops than the one who can repeat, word for word, the contents of the most exhaustive treatise on materia medica and therapeutics The medical officer with a full knowledge of hygiene and sanitation and endowed with the faculty of making a rational, practical use of it is preferable to the most expert clinician, as in military practice it is more important to prevent than to treat disease, no matter how successfully and scientifically the latter may be conducted The all-around medical officer must be a good mechanic, he should know how to use the carpenter's and blacksmith's tools, how to row and sail a boat, how to make a raft and occasionally he will have reason to be thankful if he has learned how to pack a mule and drive an ambulance team His miscellaneous knowledge of matters and things entirely outside of his legitimate province will be constantly drawn upon from different sources and the more he knows and is willing to impart the more he will be useful and popular The man who enters the medical department of the army under an impression that he is only expected to treat wounds, set broken bones and prescribe for the ordinary camp ailments makes a serious mistake and will be surely a disappointment both to himself and to those he is expected to serve

Transfer of wounded to the hospital ship *Relief* at Arroya

Physical condition—The ideal military surgeon in possession of the necessary mental and physical qualities to make him so is seldom seen The most active brains are often found in a frail body I have often seen in civil life surgeons of great reputation struggling with disease or its effects, or the victims of some congenital or acquired defects, who were wonders in the operating amphitheatre in spite of such disability I have seen more than once the saddest of all spectacles in professional life—a surgeon, himself the subject of an incurable disease, muster into service every particle of his reserve strength to perform a critical operation with a view of saving the life of another Achievements of this kind are possible in private practice but are entirely out of the question in military service The physical condition of the military surgeon must be as nearly perfect as possible A physical examination as thorough and as painstaking as in the case of a private can only decide upon the necessary physical qualifications of candidates for commission in the medical service For good reasons this rule is followed in the selection of medical officers for the regular army and there is no ground why the same requirement should not be exacted in the National Guard During my service at Chickamauga and in the Cuban campaign, I saw more than one volunteer surgeon who ought to have been excluded from the service for physical disability During a campaign the loss of a single medical officer may prove a great disaster Of all commissioned officers the surgeon is the most indispensable The vacant place of a line officer can be filled at a moment's notice without any serious loss to the service, not so with the surgeon His position is one requiring special training and one that can not be filled without crippling the medical service at some other point For this, if for no other reason, the medical officer must be in sound health and able to cope successfully with the hardships of a campaign In battle, and during the prevalence of an endemic or epidemic disease, the medical officer is the one above all others whose strength and endurance are taxed to their utmost extent His services are required by day and by night He has no rest, and unless in possession of an iron constitution, his strength fails him and he becomes, if not a fit subject for the hospital, at least a physical wreck, who, if he persists in continuing his work, will often do more harm than good A number of such instances came to my personal notice during the Cuban campaign A medical officer should not only be in full possession of health and all that this implies, but he should have been in training to endure hardships of all kinds from early childhood He need not necessarily be an athlete, but he should be able to walk twenty miles a day or ride forty without fatigue and then be ready to do a night's work should an emergency demand it The dancing halls and club houses are poor training schools for a successful military career The labor and hardships



The Spanish military hospital in Ponce, Porto Rico encountered in hunting are best calculated to prepare the body for a life of great activity and privation Frugal living will not only prove conducive to the maintenance of health but will be the best means of initiating the surgeon to the uncertainties of the commissary department when on the march or in the field

Let every one who chooses the military career dispense with unnecessary clothing and luxuries during early life in order to accustom and adapt himself for his life work, which in time of war will bring the inevitable amount of viscissitudes and even suffering The medical officer must be a good horseman, which here not only implies a good rider, but a knowledge of the usual ailments of horses, the treatment, feeding and care of the animals To sum up, the military surgeon must be a man of vigor, made so by birth and training, with as few requirements in his habits of living as possible, in order that he may resist to the highest degree the influences of climate and disease and prepare himself for the hardships and privations incident to active warfare

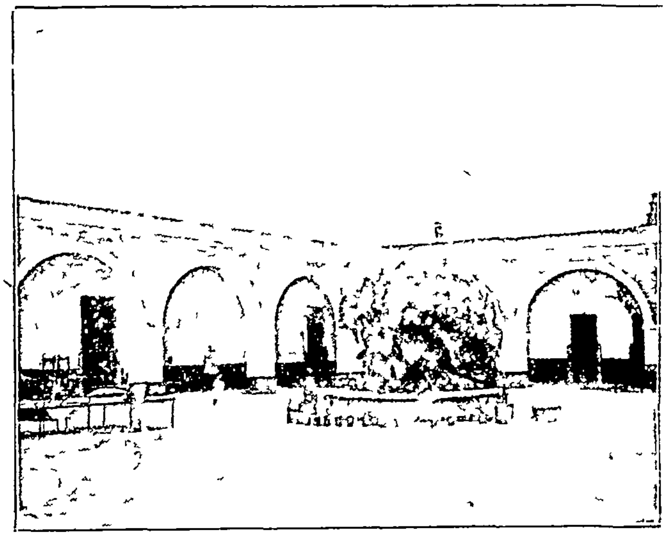
Mental qualifications —A proper and adequate preliminary education is exacted of every surgeon in the regular army, without it he is not permitted to pass the medical examination Statistics show that a large percentage of the candidates are dropped at this stage of the examination This is a reflection on the system of medical education which continues to prevail in our country About the only evidence of proficiency the National Guard surgeon in most of our States is required to show is his diploma It makes but little difference when the diploma was obtained Evidences of a satisfactory preliminary education are not required In consequence of such an easy entrance into the medical service of our State troops many of the men who receive commissions are illiterate By hard post-graduate work they often become good physicians, but they seldom if ever make up for the early defects of their education, which seriously interfere with a successful military career Is it to be wondered at that when such shortcomings are discovered by their colleagues and officers of the line, they do not command the respect their commissions, should entitle them to? The reports made out by such men speak for themselves, and appear as black stains upon the department they represent The elevation of the standard of medical education by most of the medical schools throughout the country will gradually wipe out this blemish, but it will take many years before all of the diplomas can be accepted as sufficient proof that their possessors are entitled to recognition by the medical department of the different States Let us hope that a speedy and radical reform may be instituted in the different States which will accomplish the desired object, and which will make the commission of a medical officer of greater import in showing a higher degree of preliminary and professional proficiency than the diploma of any of our medical colleges This is a desideratum for the realization of which every one interested in the success and usefulness of the national guard should willingly use his influence Fortunately, there are no specialties in military practice The medical education of a military surgeon must be of the most liberal and broadest kind His practice is so varied that he may have to be physician, surgeon, oculist, aurist, etc, the same day The sphere of the regular army surgeon serving at a post includes in addition obstetrics, gynecology and diseases of children Every military surgeon must be an expert in physical diagnosis and examination of the eye and ear He must know something about dentistry, he must know how to extract teeth and how to put in a temporary filling in a carious tooth that can be saved He must be familiar with neurology, the use and application of electricity as a diagnostic and therapeutic resource In camp and field he is limited to his own resources in the diagnosis and treatment of all kinds of injuries and diseases He must therefore be well equipped with a thorough knowledge of everything pertaining to surgery and medicine, and is often called upon to represent the different specialties No amount of preliminary and professional education will make the military surgeon an efficient officer unless he is possessed of an inborn aptitude for the profession He must be able to apply and make use of his knowledge Many men of great learning never become successful practitioners Their store of knowledge fails them when they come to apply it The military surgeon in camp and field must be a man of quick perception He must be able to recognize malingering as well as disease In an emergency he must be in readiness to act intelligently at a moment s notice Hesitation is dangerous both to the patient and the reputation and good standing of the surgeon. Indecision creates mistrust, procrastination disaster. Quick decision and prompt action are the essential prerequisites of successful emergency work. Successful action, however, must be preceded by thoughtful, systematic preparation. The most successful surgeon is the one who adopts and follows the watchword, *semper paratus*. He should never be caught napping. Careful preparation makes prompt action possible. The successful surgeon makes his plans ahead and supplies himself with the necessary outfit, medicine, dressing materials and instruments before the emergency arises, and when it does so he is fully prepared to meet it. A lack of forethought and systematic preparation accounts for many shortcomings of medical officers in the field and camp, with the necessary evil consequences for those entrusted to their care.

Military spirit.—Any one who enters the medical service of the army as a life avocation will be disappointed unless he does so imbued with a proper military spirit. The military surgeon must be a military man and an integral part of the army, if he wants to do justice to his calling and the department he represents. I fear it is a lack of the proper military spirit in some of the medical officers in the regular army that is responsible for a well recognizable cleft between them and the officers of the line and field. If this is true in the regular army, it is only too obvious in the National Guard. The rank of the medical officers and their standing in military and social circles suffer when they are regarded and treated as an ordinary doctor. The West Point graduate, educated at the expense of the government, too often forgets that it takes more hard work and a longer time to make a good doctor than an officer. The officers of the National Guard, holding commission by the grace of their governor, do not realize sufficiently that their military surgeons have spent a small fortune and five years in acquiring a knowledge of their profession. They seem to forget, or at any rate often ignore, that when they go into camp or in the field they do so at a great personal and pecuniary sacrifice. Their absence from home, even for a short time, may cause a break in their practice difficult to repair. The medical officer is entitled to recognition as a military man, and if this is not accorded to him voluntarily, he must resort to measures that will enforce it. The lack of military dignity on part of the medical staff is due largely to a lack of the proper military spirit in the members which compose it, and to too great a familiarity between the surgeons and the officers and men. The correction of these evils can not be undertaken too soon, and when accomplished will add much to the dignity, influence and efficiency of the medical department of the army and State troops.



Court of the Spanish military hospital in Ponce

The medical officer who has enjoyed the advantages of an early military training in a military academy or the national guard, is the one best qualified to enforce military rules and assert the dignity of his position.

Punctuality.—The busiest men have always the most time to perform a duty or to meet an engagement at the appointed time. This rule holds good in all walks of life. The drones are always behind. In military life punctuality means everything and from this exaction the medical officer should never be excluded except for special and well founded reasons. In the regular army there is a way of disciplining the medical as well as other officers in coming to time in the performance of definite duties and in making out the reports. My long experience in the National Guard service has taught me, occasionally in a painful way, that the surgeons are often entirely oblivious to the matter of time, especially in the matter of making out and transmitting the regimental reports. It is the men who put off for tomorrow what should be done today, and who meet their engagements at one o'clock or thereafter instead of twelve, that render the life of their superior officers one of misery and full of disappointments. The men that accomplish the most are always ready and on time. The medical officers must be made to understand that a due regard for punctuality in performing their duties, in meeting appointments and in mapping out and forwarding reports is one of the most essential features of a successful military career.

Transfer of patients to the lifeboat in the harbor of Ponce

Courage.—It is still the general belief that, in times of war the military surgeon is exposed to less danger than the soldiers and officers in command. That this is not so is shown by the statistics of all wars. Although the position of the military surgeon is behind the fighting line, he is usually near enough to the enemy when serving in the front to be reached by stray bullets and bursting shells The number of surgeons killed and wounded in the performance of their duty in rendering first aid is by no means small in any war of magnitude In active warfare, however, the greatest danger to the surgeons is to be found in their constant exposure to contagious and infectious diseases, which follow large armies in all climates and during all seasons of the year To enter a yellow fever camp, to my mind, calls for more courage than to lead and command the troops in the battlefield Disease always claims more victims than bullets, and this is especially true of the present war with Spain The nation worships the heroism of those who fell before Santiago, but much less is said of the vastly greater number stricken down by disease, and who have lost their lives from disease, often after prolonged and intense suffering To the credit of the medical officers of this and other wars it must be said that they showed no fear, either in facing the enemy or what is vastly worse—disease When yellow fever made its appearance among the troops around Santiago, every man remained at his post and faced the danger without flinching Men from the North who had never seen the disease accepted the detail for duty in the fever hospitals without a word of complaint The medical officer must be endowed with more than ordinary courage to face the many dangers that surround him on all sides during every campaign Patriotism begets heroism and I make a well-founded claim for both for the medical profession represented in the army

Personal habits —The old adage that "It is easier to preach than to practice," is a familiar one and should be made to apply with the same force to doctors as preachers The first and most important duty of the military surgeon is to prevent disease This can often be done more effectively by example than by precept The military surgeon must guard the camp against disease He is looked upon and must be regarded by those under his care as the one above all others who can give them advice in matters pertaining to their health He is expected to do this by example as well as precept He must become a permanent object lesson in inculcating the importance of cleanliness in person and in dress His tent should be the cleanest and most orderly in camp Temperance in eating and drinking can be taught more successfully by action than by words A military surgeon under the influence of liquor will do more harm in encouraging the vice of intemperance than can be undone by weeks of lecturing Profanity is prevalent in every camp and while it is not the duty of the surgeon to supplant the chaplain in suppressing it, it should receive no encouragement by his example In his conduct toward the men the surgeon should be firm and dignified, yet kind and sympathetic, especially to those in need of his professional services An impetuous nature and an irritable temper create a rebellious spirit, which it is difficult to control by the most energetic measures Proper questions should be answered willingly and with sufficient clearness and adequate length to furnish the desired information, and not gruffly and snappishly, as is occasionally done without any reason or provocation Overwork and a disordered digestion are poor excuses for treating a subordinate in an undignified, ungentlemanly manner The military surgeon must be known in camp as a gentleman, not only by the officers but by every man under his charge, if he expects to be respected and to do justice to his high calling and responsible position

The military surgeon in war —The true qualities of the military surgeon are crystallized and best known during an active campaign It is in war that his ready resources will come to the surface and will be subjected to the severest tests It is in battle and during the prevalence of devastating diseases that his moral courage and physical endurance will be most severely tried It is under such circumstances that the troops will look to him most confidently as their protector and nearest and dearest friend It is not in peace but in war that the bond of true comradeship becomes tighter and tighter between him and the officers and men It is on the march in camp, and on the battlefield that the important function of the military surgeon receives the recognition to which it is entitled It is the wounded and the sick in a strange land that look to him for help and restoration to health It is the surgeon who so often receives the last message of the dying

The first and most important duty of the military surgeon during active warfare is to prevent disease and unnecessary suffering by giving early advice and resorting to timely precautions The location of camps, policing of the same, the water supply, food and clothing are subjects which must receive his early and earnest attention In this work he should receive the hearty co-operation of the officers in command and if this is not the case he has the moral and military authority to demand it It was not the medical department, but the arrogance or stupidity of the commanding general of the invading army that is responsible for the extensive outbreak of yellow fever during the Cuban campaign This experience is sufficient to teach commanding generals that it is unsafe in the future to follow such an example, as an imprudence of this kind, giving rise to inexcusable slaughter and indescribable suffering, will meet with universal indignation The military surgeon is in reality the family physician of the men placed under his charge He attends to the little ailments with the same care as though he had been sent for by a wealthy family and expected a handsome fee To be successful in the treatment of disease he resorts to the simplest medication Complicated prescriptions are dangerous and absolutely out of question in military practice The tablets containing drugs in the most concentrated form are a great blessing to field practice and should be relied upon almost exclusively in the treatment of disease The remedies needed are few, and if well chosen and applied will answer all indications A liberal supply of quinin, opium, calomel, strychnia, camphor, iron, arsenic, bicarbonate of soda and bromid of potassium will leave but little to be desired Turpentine, castor oil, alcohol and the anesthetics are about the only fluid medicines the military surgeon has any use for The breakage and waste in dispensing medicines in bottles are inexcusable in modern field work Fancy drugs and preparations should not be tolerated In the practice of surgery the military surgeon who wishes to attain the maximum success must be conservative Strict asepsis and conservatism are the two things which are *destined to make* miltary surgery successful Every surgeon must have special training in emergency work He must be perfectly familiar with the indications and technique of every operation which may become necessary in the field He seldom will have an opportunity to cut for stone, extract a cataract, remove an ovarian tumor or operate for other benign and malignant growths, but he must know how to treat a compound fracture in the most modern and approved manner, he must be skillful in the treatment of wounds of all kinds, and he must be a master in performing an amputation and in ligating arteries in any part of the body He must learn to perform all emergency operations with the simplest facilities and fewest instruments possible, in order to adapt himself in time to the exigencies of war The surgeon who can extemporize an operating table in the field and who can secure asepsis with the use of the camp kettle, soft soap and carbolic acid or sublimate and who can perform the most difficult operations with the simplest and fewest instruments, with little or no assistance, is the one who will accomplish the most and who will obtain the best results in the field

Ponce, Porto Rico, Aug 8, 1898

TREATMENT OF RETRODISPLACEMENTS OF THE UTERUS BY SHORTENING THE ROUND LIGAMENTS PER VAGINAM

Presented to the Section on Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10, 1898

BY J RIDDLE GOFFE, M D
PROFESSOR OF GYNECOLOGY NEW YORK POLYCLINIC VISITING GYNECOLOGIST TO CHARITY HOSPITAL, ETC
NEW YORK N Y

Dr Howard A Kelly, at the recent meeting of the American Gynecological Society at Boston, announced in a discussion that he had collected a list of forty-five different operations that had been suggested for the relief of retrodisplacements of the uterus Accepting this statement as true, what more suggestive fact could we have of the importance in which this affection is regarded by the profession, or of the assiduity with which the profession has devoted itself to its relief?

Much has been learned regarding the dynamics of the female pelvis, but much still remains to be discovered Plates representing saggital sections of the female pelvis taken from frozen sections have been transmitted from one generation of text-books to another, and the errors therein depicted have likewise been transmitted from one generation of medical men to another The section of a frozen pelvis represents the relation of the parts in that individual only, and in all probability does not correctly represent the relation of these parts during life It is a recognized fact that the uterus rests in a position of unstable equilibrium, varying in its position with every movement of the body and with every respiration, so that the average position of the uterus as obtained after an examination of many living women is the only way of reaching a conclusion as to even a proximal ideal position A great advance was therefore made in definite knowledge upon this subject when an investigation was instituted for the purpose of more positive information by examining *living* women, while standing in an erect posture By this method of investigation it has been reliably determined that when a woman is upon her feet, and that is the position in which all great effort is made and the forces brought into play which tend to retain or remove the uterus from its normal position—it has thus been determined that when the body is in an upright posture the uterus normally rests upon its anterior face and is suspended in a cradle or sling of tissue reaching from the symphysis pubis to the sacrum, known as the vesico uterine ligaments in front, and the utero-sacral ligaments behind The uterus is steadied in this position by the broad ligaments, reaching from either side of the pelvis to the uterus, and the round ligaments, which tend to restrain the uterus in its anteverted position, and indirectly to support the broad ligaments

Accepting, then, the broad principle that Nature is consistent in her work, and applies to the uterus the same mechanical principle that she utilizes in supporting all other organs of the human body, we must conclude that the uterus is supported by ligaments

The uterus itself is not an organ of any great weight, and requires only delicate structures to retain it in its proper location in the pelvis It is, however, subjected to intra-abdominal pressure which must be counteracted Let us see, then, how this is accomplished Resting as it does, upon its anterior surface, or in other words, having its anterior face looking downward, it receives the intra-abdominal pressure expended in the pelvis upon its posterior surface If then the sling of tissue which sustains the cervix high in the hollow of the sacrum is sufficiently strong to retain it in that position, all intra-abdominal forces impinging upon the uterus tend to force the fundus still farther to the front, and so help to maintain its normal anteverted position We must therefore look to the tissue between the cervix and the sacrum, viz , the utero-sacral ligaments, as the chief factor in maintaining the anteverted position of this organ If for any reason these ligaments become over-stretched or relaxed, so that they lose their contractile powers, the entire uterus settles in the pelvis, and the cervix swings correspondingly to the front, thus preventing the resultant of intra-abdominal forces from carrying the fundus to the front until this stretching process has reached such an extent as to actually permit them to impinge upon the anterior segment of the uterus and eventually carry it into a position of retroversion In this process all of the ligaments gradually become relaxed as the strain is put upon them until not only one or two, but all of them lose their tone, and the uterus becomes hopelessly displaced Such, to my mind, is the rational explanation of the etiology of this affection In a normal unimpregnated uterus the round ligaments alone may be relaxed to any degree you choose and the uterus will still remain in place, the same thing may be said of the broad ligaments, but once you relax permanently the utero-sacral ligaments, and you at once set in motion the process that eventuates in retroposition

The most frequent cause of this relaxation is undoubtedly the absence of prompt and efficient involution following parturition Next in order of causation, I place prolapsed and diseased appendages, which, resting upon these structures and becoming adherent to them, so interfere with their nutrition that they eventually relax and allow the cervix to swing to the front Another and not infrequent cause is the presence of a fibroid tumor located near the uterine insertion of the utero sacral ligaments

The condition of retroversion and retroflexion is not confined however to married women In single women, especially in cases of congenital retrodisplacements, the etiologic factor is also to be found in the cradle or sling of tissue reaching from the symphysis pubis to the sacrum, but instead of being posterior to the cervix, the cause of displacement is to be found in the vesico-uterine ligaments, and more especially in the manner of their insertion into the uterine tissue Reynolds of Boston, following Foster and Ranney, and Hart and Barber, has called attention to the fact that the method of attachment of the tissues about the cervix is an important element in retaining the uterus in its normal position For example, the anterior position is maintained by the tissues in front of the cervix being inserted into it at a higher level than that at which the tissues posterior to the cervix are attached If, for any reason, by an anomalous anatomic arrangement, the tissue in front is inserted at a lower level than the tissue behind, the natural pull of these ligaments tends to throw the fundus backward This condition is exactly the one that is so often found in congenital displacements, and in fact in all retropositions of the uterus as found in unmarried women, and probably the majority of these are congenital—that is the cervix being in the axis of the vagina and the anterior wall extremely short, showing that the utero-vesical ligaments are inserted very low down This principle has been taken advantage of by Reynolds of Boston, in an operation for the relief of this condition in virgins, in which he simply detaches utero-vesical ligaments from their low insertion and stiches them to the anterior face of the uterus at a little higher level He reports a number of cases in which he has applied this treatment successfully This certainly seems a most rational procedure

In accordance with the dynamics as previously explained, however, the most rational relief of retrodisplacements is to be found in some operation which will shorten or restore to their normal condition the utero sacral ligaments An effort has been made to accomplish this by some German operator and also by one or two surgeons in our own country, but the difficulties of reaching these structures, either through the abdominal wall or per vaginam, are so great that thus far no satisfactory results have been obtained It is my belief, however, that in shortening these ligaments is to be found the proper method of treating these persistent cases Next to the utero-sacral ligaments the most rational structures to be utilized in an operation for the relief of this condition are the round ligaments While the functions of the round ligaments, are to direct and limit the excursions of the fundus from its normal position, rather than to sustain the weight of the organ and resist the pressure upon it, nevertheless experience has shown that they are quite equal to the latter offices, at any rate for a sufficient length of time to allow the utero-sacral ligaments to regain their function

Today by far the most popular operation for the cure of retroversion, and the one most frequently employed by operators throughout the country, is either the original or the modified Alexander operation The objections to Alexander's operation, however, are many 1 It has a limited field of application, being restricted absolutely to cases in which the uterus is perfectly movable and the appendages free from disease Such cases in my experience constitute but a very small proportion of those requiring relief 2 The round ligaments can not always be found at the external ring In this connection it may be noted that a number of cases have been reported in which an anomalous insertion, either into the fascia about the internal ring or at the outer border of Poupart's ligaments has been found Moreover, in many instances the ligament is so frail in this part of its course, that it does not withstand the strain necessary to draw it out of its bed and breaks in the procedure 3 The operation necessitates two incisions and two objectionable scars in the abdominal wall 4 The operation in the hands of every operator experienced in this procedure is followed by hernia in a certain percentage of cases

In order to extend the field of application of the Alexander operation so that it might include cases of retroversion with adhesion and with diseased appendages, Drs Wylie and Dudley of New York, and Dr Mann of Buffalo, have suggested and put into practice a method of shortening the round ligaments within the pelvis through an incision in the abdominal wall The procedure in the hands of these three operators differs only in the manner in which the ligaments are doubled back upon themselves The results, however, have been satisfactory, and the operation is still practiced by them all The objection to it, however, is that it necessitates a laparatomy with all its attendant discomforts and possible hernia, and in simple, uncomplicated cases is altogether too serious a procedure for so simple a condition Other operators, in their endeavor to avoid laparotomy, have opened Douglas's pouch through the vagina, broken up the adhesions, thus setting the ovaries and appendages free, and then shortened the round ligaments at the external ring

As this operation which I am doing has to deal with the round ligaments, I have expended most of my time in discussing that structure as the natural support, without entering upon the relative merits of abdominal fixation, which I believe has a certain field of application, although a limited one

With the work of these operators in mind the idea naturally suggested itself of opening the peritoneal cavity through the anterior vaginal fornix, breaking up the adhesions, restoring the uterus to its normal position and shortening the round ligaments through the one incision This has been found a perfectly feasible procedure, and has met with such success at my hands that I have ventured to urge its adoption in all cases of retro-position of the uterus, whether simple or complicated

The technique of the operation is as follows After rendering the parts thoroughly aseptic, curetting the uterus and packing it with iodoform gauze, the cervix is seized by a vulsellum forcep and dragged down to the vulva A transverse incision is made just in front of the cervix through the vaginal wall, as in the procedure for vaginal hysterectomy The bladder is then stripped from the anterior face of the uterus and the finger pushed through into the peritoneal cavity Grasping the edge of this transverse incision near its middle point by two artery clamps, the anterior vaginal wall is put upon the stretch and the longitudinal incision is made in the anterior wall throughout its whole extent The bladder is then dissected off the vagina for a distance of half an inch either side of this longitudinal incision The purpose of the latter incision and the separation of the bladder is to secure sufficient room through which to work The dissection is done almost entirely with the handle of the scalpel and the finger, and the hemorrhage is inconsiderable

The finger is now passed over the uterus and by careful but persistent efforts the adhesions are broken up, both those to the uterus and those to the appendages By hooking the index finger over the broad ligament near one cornua of the uterus, the latter organ is gradually delivered into the vagina The ovaries and tubes are readily drawn down afterward, where, in full view and of easy access, they can be treated in whatever way may be indicated The diseased portions of the ovaries may be resected, portions of the Fallopian tubes removed, or the appendages of one side may be removed and conservative work done upon the other side, or if the appendages of both sides are found hopelessly diseased, they and the uterus can be easily removed

The proximity of the horn of the uterus to the vulva enables a ligature to be applied about the appendages and as near to the fundus as may be desired After the appendages have been cared for, the round ligament, first of one side and then of the other, is caught by an artery clamp from one to one and a half inches from the horn of the uterus and dragged down in the form of a letter "U" In this position a fine braided silk ligature is passed through the ligament at as remote a distance from the forceps on the outer side as will allow approximation when it is passed through the ligament near to the horn of the uterus It is then tied, thus shortening the round ligament to an extent equal to the length of tissue taken up in the loop Two other smaller sutures are passed between this one and the forceps, and finally a third one, catching the tip of the loop and attaching it to the anterior face of the uterus just at the origin of the round ligament The horn of the uterus thus treated is allowed to resume its position in the pelvis, the other horn of the uterus drawn down and the round ligament of that side treated as in the first instance The uterus is then allowed to take its normal position of anteversion, and the bladder tissue that was dissected from the uterus is adjusted in its original position The tissues are not sutured to the uterus, but a running catgut suture is applied through the extent of the longitudinal incision The vagina is then comfortably packed with iodoform gauze and the operation is completed In cases of congenital retroversion not only are the round ligaments shortened by this operation, but uterine insertion of the utero-vesical ligaments is carried up on the anterior face of the uterus and the abnormal anatomic arrangement previously described is thus remedied

The commendable feature of this operation is its wide application Simple [illegible] version of the uterus can be relieved by the [illegible] of a properly fitting pessary, and it is a question whether the condition demands the application of any surgical procedure beyond that The circumstances of the individual case, however, must determine action in that direction The chief point of attention is the complications attending this condition Through the anterior vaginal wall all complications can be readily dealt with, from the simple removal of diseased appendages throughout the whole range of conservative procedures, and even to the extent of myomectomy for small fibroids and ovarian cysts of all kinds During the past winter I have operated upon cases of retroversion with fixation, complicated by simple cysts of the ovary, by purulent cysts of the ovary, by pyosalpinx, and in one instance by a dermoid cyst containing about a quart of material

Now as to results The total number of cases submitted to this operation is thirty-one The first operation was done in March, 1896, and the last done in May, 1898 In all my cases of simple retroversion treated in this way the results have been entirely satisfactory, not only in the anatomic cure, but also in the complete removal of all symptoms Of these cases there have been six I have had one case complicated by a dermoid cyst and five cases complicated by adhesion, club-shaped Fallopian tubes and cystic ovaries In all these cases the ovary has been resected and the Fallopian tube amputated In all the other cases the appendages of one side have been completely removed for destructive diseases of those organs, and in about one-half of them conservative work has also been required upon the remaining appenages Of these cases, one patient from whom the appendages of one side were removed became pregnant shortly after the operation and was delivered of a healthy child in September, 1897, after a period of five years' sterility This patient has been examined by me since and the uterus found freely movable and in perfect position

A second patient, in whom conservative work was done upon the appendages of one side, the appendages of the other side being healthy, after a period of four years' sterility and intense suffering, became pregnant shortly after the operation, and since my arrival in Denver I have learned through my assistant that she has been delivered of a child weighing nine pounds, and that she has passed through this gestation with greater comfort than any of the three previous ones

A third patient is now pregnant five months In this case the appendages of one side were removed and the round ligaments shortened as usual She reports no unusual symptoms during her gestation up to this stage

As to absolute and partial failures After having done the operation a number of times, it occurred to me that perhaps it would be an improvement upon the usual method of shortening the ligaments to free the ligament from its bed, double it upon itself and then allow it to retract beneath the peritoneum To accomplish this an incision was made through the anterior face of the broad ligament just over the round ligament, and an aneurysm needle passed underneath the round ligament and slid back and forth to free the ligament from its bed The ligament was then drawn out, doubled upon itself and stitched, and allowed to retract beneath the peritoneum

In the first case this maneuver was attended by some hemorrhage, but not enough to deter me from applying it a second time In the second case, however, a hemorrhage occurred, not alarming in its extent, but most persistent in its character This hemorrhage came from the blood vessels accompanying the round ligament in its course After trying various methods of controlling the hemorrhage without destroying my work, I despaired of success in this way and concluded it was best for the safety of the patient to at once remove the uterus, which I did That was the only case in which any hemorrhage, even of an annoying character, has attended the work It was due to the modification which I adopted and which was promptly abandoned

In the cases in which it became necessary to remove the appendages of one side, I endeavored to economize time by drawing up a loop of the round ligament of that side and including it in the common ligature In accordance with my custom, I used catgut ligature, and have had the mortification of discovering that in two of these cases, two months after the operation, the ligament of that side has given way and the uterus has swung around to the opposite side in a position of partial retroversion Both these cases, however, had suffered from persistent irreducible retroversion, and since this accident have both been completely relieved by the insertion of a retroversion pessary Hereafter I have decided not to include the round ligament in the ligature applied to the appendages, but to go through with the routine process of shortening the round ligament upon that side as well as upon the other By doing so I believe that the accident referred to can be avoided All of the other cases have been completely relieved of symptoms, and when last seen were anatomically cured

The more experience I have with the operation the more satisfactory it becomes In not one of the cases has there occurred a single complication in the process of convalescence There has been no shock, no temperature The after-treatment is extremely simple The vaginal and uterine gauze is removed upon the fourth day, and thereafter no further treatment is required except a daily vaginal douche

DISCUSSION

Dr Albert Goldspohn, Chicago—I congratulate the doctor on the commendable work he has been doing in this direction The efforts of attending to the indications for pathologic conditions in the female pelvis through the vagina, originated, we may say, with Duhrssen, Mackenrodt, Aug Martin, of Berlin and others, and are somewhat repeated in the operation described here I have done the same operation about a dozen times without difficulty I consider it a feasible operation, and certainly one to be esteemed above those other unsurgical procedures which need to be relegated to the past I mean ventrofixation, vaginofixation and ventrosuspension These procedures are repugnant theoretically and practically to surgical instinct, and I am surprised that people of so much scientific common sense as the Germans should be the fathers of these procedures We need such loans from the domain of pathology, for some extreme cases of prolapse, for instance I will not totally condemn any one thing that was ever done by rational physicians with repeated success

Doctor Goffe is not entirely correct in placing the symphysis pubis at a lower level than the tip of the coccyx in the standing woman That is an error The dynamics with relation to the genital organs as stated by him are in the main correct But intra abdominal pressure must be carefully defined if we would escape objections from our opponents in this question The reason why I have not more frequently done vaginal shortening of the round ligaments or vaginal fixation of the round ligaments, as now done chiefly by Wertheim, of Vienna, is because we need to adopt a different plan in our indications of operating for displacements of the uterus and its appendages The reason why so many cases are not wholly well that have been properly treated as far as the operation went, in restoring the uterus alone to normal position, is because the same treatment was not extended to the adnexæ also The majority of retroversions of the uterus have such conditions of the adnexæ that they require conservative operations as the Doctor has suggested But the reason the ovaries became so diseased in a large proportion of cases is because they were previously displaced, they were away from the lateral normal location against the pelvic wall, they had migrated toward the median line of the pelvis and to a far lower plane, where they were subjected to traumatism between the uterus and the rectum, as well as to the evils of venous hyperemia The uterus when retroverted is crowded on to the displaced ovary by abdominal pressure If, then, the displacement led to the disease in the ovary, we need to correct not merely its condition, but above all, its position also We must do something with the displaced ovary after we have resected it, secure it in normal position This requires good access to the lateral walls of the true pelvis, which is not at all obtainable by any vaginal incision For this can only intensify the ovarian displacement, but not correct it For that cardinal reason, I can not make use of the vagina anywhere near as frequently as I would The principle the Doctor states of the sacro uterine ligament maintaining the equipoise of the uterus in normal anteversion is correct, although the numerical proportion of inefficiency of the sacro uterine ligaments, as stated by him, is too great

Dr Henry P Newman, Chicago—I was highly pleased with the paper and with the stand taken by Dr Goffe Ten or twelve years ago, when this work was advanced, particularly the round ligament operation, we had very few that would sustain us in our work, many members of the profession believing it to be visionary and work that would only last for a short time At the present time it is highly commented upon all over the country The objections, however, that are met with even today that deter many physicians from adopting the round ligament operation are, I believe, simply faults in technique By making the primary incision over the external ring, thereby finding a ligament that is well developed, when it is drawn out it is the abdominal portion of the round ligament The abdominal portion of the round ligament is a different structure, is of different size, more stable and decidedly a better support than that of the inguinal canal portion of it Moreover, the inguinal canal portion of the ligament when drawn on stays in the old operation, that is, by being stretched it is frequently attenuated, is reduced materially in size, and is not the intra abdominal ligament at all It does not accomplish much in bringing and holding the uterus forward, and consequently the operation is a failure If the round ligament is drawn out on a line with the attachment of the uterus you are sure of drawing out the part of the ligament which needs to be shortened, namely, the intra abdominal portion This much and other points in relation to operating upon the external ring are features that I brought out some ten years ago, and have adhered to with most satisfactory results, and those gynecologists who have followed this method of operating have been equally well satisfied I do not think, as the Doctor stated, that the etiology of displacements of the uterus is confined to these two ligaments I refer particularly to congenital cases so called or cases that are really faulty at puberty The uterus at birth in these cases is uniformly an infantile organ, but after puberty an arrest of development means under all circumstances a puerile condition of the organ There may be a long cervix, and a fairly well developed fundus lying upon a conical cervix This is a factor in producing displacements

Dr Howard A Kelly, Baltimore—I naturally feel interested in this discussion as I have operated a great many times for these conditions I believe no surgical operation will restore *ad integrum* these tissues and the uterus where they were before If this is not accomplished by plastic operations and rest preventing a tendency to descensus, then the question is one of the best surgical operations from a mechanical standpoint I believe all these operations should be supplemented by restoration of the floor of the pelvis I do not believe that the round ligaments support the uterus They are always found kinked in abdominal operations and hence can not be supported With the uterus retrodisplaced, the abdominal force increases the trouble, while if the uterus is anterior it increases the anterior displacement A thread applied to the fundus holds it in this normal position and the pressure then falls upon the posterior surface The floor should then be restored I have operated through a one and a half inch incision over four hundred times, and only about 2 per cent of the cases relapsed About twenty of the women have become pregnant All are doing well but one, and in her case agglutination occurred Fixation is not the proper procedure for these cases, it is suspension that is required None of the cases died Severe pain has not been noted in any case I do not include the fascia or muscle in my stitch, but only the peritoneum and subperitoneal tissue

W B Craig, Denver—I would like to say a few words in support of the Alexander operation I have had no experience with vaginal fixation, but have performed the Alexander operation in nearly a hundred cases I have been looking for some of the accidents and dire consequences which I read of in the medical journals, and I am glad to say to you that I have been disappointed I know of no case of hernia following any of my operations, and I kept track of the majority of my cases No dire consequences have followed from infected ligatures, or cases of sepsis from any cause In a body of this character these operations are purely technical If we are attempting to instruct the general practitioner who is rapidly becoming accustomed to surgical work, both special and general, then the matter takes on a different aspect Any surgeon or student with a little preparation can do an Alexander operation with comparative safety, but it takes an expert to do a vaginal operation, especially of the nature of those described here this afternoon Of course, the old method in the Alexander operation has been discarded I do not believe the time will ever come when abdominal section will be absolutely without mortality This operation (the Alexander) has practically no mortality In my series of cases I have had possibly one case of recurrence of displacement Dr Kelly struck the keynote when he said that anything that will hold the uterus forward for a short time until we get what is known as involution or reduction in the size of the organ will effect the purpose It is much simpler to make an inch and a half incision in the groin than in the belly, as we do not have the risk of adhesions, of volvulus and other occurrences which occasionally follow the most careful abdominal operation

S C Gordon, Portland, Maine—There are two or three points in connection with Dr Goffe's paper that I wish to touch upon I doubt very much the proposition made by Dr Goffe that the utero sacral ligaments have much to do in supporting the uterus It seems to me the broad ligaments have very much more to do with supporting the uterus than any thing else In relation to the support of a uterus which has a certain amount of descensus, it seems to me that we must have something at the top in one way or another to hold it forward The only exception I would take to Dr Kelly's method is that I would use catgut instead of silk, feeling sure then that I would have nothing which was going to act as an irritant and produce trouble afterward After all, if union of the peritoneal surfaces is desired, it may be obtained by good catgut, and you have an absorbable material which is taken care of, so that between Dr Kelly's operation and the operation for shortening the round ligaments, I should confine myself to those two, and should always do them through an abdominal opening I am not much in favor of vaginal operations for remedying or treating these conditions We can treat these conditions so much better through a small abdominal opening than by resorting to the long process described by Dr Goffe I do not like it, but Dr Goffe does I have no doubt I do believe, however, that through a small abdominal opening we can get at things and do them much better, we can do conservative operation upon the ovaries and tubes and put them up where we want them But it seems impossible to me when we resort to the vaginal operation Then, again, no vaginal operation can be done without resulting more or less in the formation of scar tissue which may become a source of pain So the point is this with me Abdominal section with fixation or shortening the round ligaments by either the Dudley or Mann operation, Mann's preferably, fix the uterus forward a little while and the thing will take care of itself

Dr Henry O Marcy, Boston—At one time I was very enthusiastic in regard to the Alexander operation I was one of the first surgeons in this country to adopt it and have had considerable experience with it, and have utterly abandoned it It is a popular operation with us in Boston, but as I have seen so many cases of hernia that have presented themselves to me after this operation, I am compelled to believe that it is the exceptional operation that we should do It may be advisable to do it under certain conditions, but the surgeon must know the condition of the pelvic structures We know that in the vast majority of cases there is something besides the mobility of the uterus with which the surgeon has to deal, and that something is an unknown factor unless we open the abdomen For years I have adopted the method of opening the abdomen, as advocated by the last two speakers, determining the factors with with I had to deal, and instead of using silk, as I believe Dr Kelly does, I use the animal suture on either side close to the cornu of the uterus, making double fixation I believe Dr Kelly puts one suture into the fundus and another a little posterior to it There is considerable advantage in placing sutures on either side, it does well in my hands, and whatever means we resort to we should be careful as to the other factors, to wit, the endometrium, the cervix, the perineal structures, and look after the circumferential factors as well as the one condition of malposition of the uterus proper

Dr Charles I Bonfield, Cincinnati—In regard to the etiology of these cases, it seems to me Dr Goffe has very much exaggerated the role the utero sacral ligaments play in supporting the uterus If any of you will take a case where the uterus is in its normal position, pull it down to the vulva, and take pains to introduce the finger into the vagina and feel where most of the traction is made, you will find it is not altogether in the posterior cul de sac

Another point is the normal tone of the structures that hold all the abdominal organs in place Most of you must have observed cases of slight ventral or inguinal hernia in which it was considered unnecessary to wear a truss, and yet when these patients became run down in health and the tissues became lax the hernia gave much more trouble When their health was improved again their hernia practically disappeared I have had cases that have gone on for five or six years without a truss who had worn it for years They become ill with pneumonia or typhoid fever, and again the truss has to be worn This is a factor which should be considered in treating uterine displacements

Dr Milo B Ward, Kansas City—I can not see how it is possible for us to make such a bugbear of entering the abdomen and dissecting the vagina, bladder and uterus with perfect impunity It seems to me, every case of retrodisplacement or of retroflexion can not depend upon the utero sacral ligaments A retroversion may do so, but certainly not a retroflexion If you put your finger in the cul de sac of Douglas the uterus will fall back quickly if you do not keep it there The utero sacral ligaments have nothing to do with it Every case of retroflexion is pathologic only when adherent by some condition of the appendages holding it there or a fibroid in that portion of the uterus lying next to the cul de sac So we must do something with the appendages in all cases That being true, we must go into the abdomen I can not, I am sure, go into the vagina as the essayist can and bring forward adherent appendages by looping the finger over the fundus of the uterus, because I find in hysterectomy, while I have gotten the position before and behind me and have every opportunity to get in behind the uterus, I use a hook to bring it forward, I can not do it with my finger If we operate through the abdomen, which we ought to do in nearly all cases, we can shorten the round ligaments as it is done in New York and other places, or as I have done it in my operations I loop the round ligaments to the anterior aspect of the uterus thereby shortening them This can be done in a minute or two with kangaroo tendon, it is perfectly safe, and holds the uterus a short time until the pubic bone becomes stiffened, and it remains as long as you want it I do not believe the Alexander operation is applicable in these cases, because if we do the operation at all, we are doing it on a case that is not very pathologic, for the reason the uterus is movable, and pessaries will act as well as an operation and are certainly much safer

Dr William H Humiston, Cleveland, Ohio —As I stated a year ago, I have not used the Alexander operation, for the reason that if we have disease of the adnexa the case can be cured without that operation If you have a misplaced organ for a number of months or a year or more, if the diseased condition is continuous, there is a change in the tubes and ovaries, and by bringing the uterus forward, after having curetted the diseased mucosa and reduced the size of the uterus, it will remain in place if supported six or eight weeks by a pessary The majority of cases of retrodisplacement of the uterus only exist for a short time and can be cured simply by placing the uterus well forward and supporting it for a few weeks with a pessary, then the pessary can be removed and the uterus will remain in place If you have changes in the adnexa, then the uterus is liable to go backward again Therefore, in the Alexander operation you have a movable uterus, you must have the appendages healthy or the mere shortening of the round ligaments is not going to relieve symptoms If you have displacement with healthy adnexa, the Alexander operation is not indicated, and mild curetting and placing the uterus forward are sufficient In cases where we have diseased adnexa, I open the abdomen for the purpose of examination I anchor the uterus forward, and use kangaroo tendon with which to hold the uterus to the abdominal wall I do not scarify It will hold the uterus there a sufficient length of time for the adhesion to take place It is elastic and it will relieve the case

Dr W O Henry of Omaha—I can hardly agree with the essayist regarding the anatomy that he gave either as to the position of the symphysis pubis when the patient is standing or as to the importance of the attachments, both anterior and posterior

In regard to the operation of Dr Goffe, I should say it is a difficult one, and an unnecessary one as a rule Personally, I prefer to open the abdominal cavity and attach the uterus after the manner recommended by Dr Kelly, by the slender peritoneal attachment, and I think the remark he made should be emphasized, because I believe there are many cases in which bad results have occurred after ventrofixation In such operations as ventrofixation, where the peritoneum is scarified, we get an absolutely immovable uterus But when a silk ligature is introduced through the entire thickness of the abdominal wound, you get a strong enough peritoneal tissue to hold the uterus in place Where there are no adhesions and the peritoneum is all right, where the uterus is not necessarily large, no operation is needed In many cases the uterus can be replaced and patients cured of their trouble by the use of a suitable pessary I believe in the use of the pessary in such cases, but where an operation is necessary I still believe in operating by the abdominal method I open the abdomen, attach the uterus by two ligatures to the abdominal wall If you have two ligatures within each other you are likely to get a dropping into a little nook a piece of omentum or bowel, strangulation taking place, and necessarily you will have to reopen the abdomen A single ligature for suspending the uterus will generally answer in the majority of cases

Dr George J Engleman, Boston—The subject under discussion is a very broad one, and we all have our preferences My own preference has been to attempt to restore normal conditions as far as possible, and not to replace one fixation by another, and, of course, fixations are now largely given up, likewise suspension We must all yield to Dr Kelly's success and the number of his cases From close observation extending over quite a long time we must all admit that fixation is injurious unless it is resorted to in older women, where possibly the appendages have been removed and prolapse has occurred I have seen a number of cases in which the delicate ligament has been stretched four or five inches or more, and yet it did not accomplish the object If the good is accomplished in a given time, say in two or three weeks, I have no doubt the ligament holds But frequently it is elongated more and more, and unless the normal conditions are restored, the operations are failures I have preferred the shortening of the round ligaments with the restoration of other co existing conditions It has appeared to me that if we repair an old door we must repair the hinges, not nail it down either open or closed, but restore it as far as possible to normal conditions, and for that reason I prefer the shortening of the round ligaments through an abdominal incision in order to deal with the appendages, which in so many cases are at fault

Dr James H Etheridge, Chicago—I have finally settled down for the past three or four years to abdominal fixation Personally, I think there is very little difficulty in doing an operation through an inch or an inch and a half incision As to ventrofixation, I have done many operations of this kind with only one abdominal suture I suture through and through the abdominal wall, and one intra abdominal suture is all I generally use in doing this operation I have observed throughout this discussion that but very little allusion has been made to Dr Goffe's paper I am very glad to have heard Dr Goffe's paper, because it is something new, and I want to hear what he will have to say three or four years from now I still think I shall continue to do the abdominal fixation operation

I am very much impressed with Dr Ferguson's idea of suspending the uterus in this way I cannot but believe that something will occur in loosening the stumps around the ligament, and they will slip back into the abdomen, one side or another He says that is the fault of the operator or in the technique of our operations If that occurs, he is hopelessly in the minority in the way of getting a reasonable expectation of good results from it

Dr Joseph Price, Philadelphia—In regard to the precise position of the ligature in these operations by Dr Kelly, it has been disputed thrice or more by good men practicing the operation, each criticising one another's technique One inserts the suture at the fundus or posterior to it, and the other a little more anterior Thus, a paper was read by Dr Ashton, one by Dr Penrose, and I think a third by Dr Noble, each differing in the mathematical degree of position of the ligature

Dr James H Etheridge, Chicago—I understand Dr Kelly uses silk, and Dr Gordon catgut I have always used silk worm gut, leaving it in three weeks, taking out the abdominal stitches at the end of eight or ten days, and leaving the through and through silkworm gut stitches in three weeks From past experience I have had in digging out silk material and other things from sinuses, I have gradually given up the idea of leaving a fixed suture in the uterus

Dr C E Ruth, Keokuk, Iowa—I have had considerable experience and some disappointments in trying to relieve uterine displacements I think a pessary has its place in suitable cases Had I known what the condition of the uterine adnexa was, I am quite sure I could not so well deal with the adnexa through the incision which Dr Goffe makes as I could through an abdominal incision I have done quite a number of ventrofixations that were very unsatisfactory, so far as relief from the symptoms was concerned for which the operation was done, and I have practically abandoned the operation for a year and a half, not believing that it should never be done, but I have not found a case in that time in which I thought the operation was indicated I have since done it a few times but I very much dislike to substitute one pathologic position for another I am very slow indeed to believe that all cases of uterine retroversion and flexion are pathologic and demand treatment I believe we will better subserve the interests of our patients and own reputations if we make a small abdominal incision, and be certain as to the existence of a pathologic condition of the uterine adnexa As to leaving unabsorbable materials in the abdominal cavity, I am less and less in favor of it as the years go by

Dr Joseph Eastman, Indianapolis—There is one point that was touched upon by the last speaker and Dr Etheridge with reference to leaving material, such as sutures which is not absorbed, and which I think is important Silk, for example Recently Dr Tait has abandoned using anything else but silk For a number of years I have boiled my silk, and then added quite a strong solution of carbolic acid to it I have no trouble in digging out silk, and I think Mr Tait resorts to a similar method I do not think we should abandon silk altogether in our intra abdominal work

Dr A H Cordier, Kansas City, Mo —I desire to offer a mild protest as to the ease with which the essayist would have us believe that this operation can be done through the vagina I feel very much safer to make a small incision in the abdomen, open from above and remove the adhesions While I use silk in all my abdominal work in the peritoneum, the placing of the silk ligature is an important thing If the silk ligature should become infected at any time in the future in the position here (illustrating), it would find its way out through the bladder two or three months later if buried in the tissues That would be a serious objection to the use of the buried silk suture in between the uterus and bladder itself I would also disagree with the position of Dr Ferguson in regard to making three openings in the recti muscles, because he takes a portion of the round ligament that stretches during pregnancy, shortens it up, so that he has nothing but two stumps to the abdominal incision, and as pregnancy advances these little stumps will not stretch like a ligament which is seven inches long running from the tubes up through a canal that is movable The Doctor will find that this will be a serious objection to the use of the operation he has so beautifully illustrated with his diagrams today Dr Goffe has presented a most excellent paper, but I wish to protest against the idea that it can be done easily with the adhesions separated and the uterus placed forward in position in a mass of intestinal leaks that will require possibly a future operation to repair

Dr A H Ferguson, Chicago—I believe Dr Goffe speaks of his method as a new operation I think if the literature is thoroughly gone over he will find that this is not correct, and in the absence of Dr, Byford, I wish to say that he presented a paper in which he described this same operation, which he does through the vagina It was described several months ago in Chicago In reply to Dr Cordier, I wish to say that there is a distinction between stretching and hypertrophy when pregnancy takes place

Dr Albert Goldspohn, Chicago—In regard to the question of priority of vaginal shortening of the round ligament, I beg leave to say that the first man who did it was a German in Dresden, whose name I can not recall It was then done by Wertheim of Vienna, from which we Americans have it Dr Byford of Chicago was the first man probably in the West who did it after those gentlemen

Dr Joseph Price of Philadelphia—Dr Kelley in his remarks spoke of pregnancy occurring in 5 per cent of the cases in which he had corrected displacement of the uterus, or 20 in the 400 cases treated by him The percentage of pregnancy following the old fashioned simple methods of correction of uterine displacement was much larger Dr Bantock records a case returning from Africa to London for the correction of a posterior displacement thrice Thrice a pessary was replaced and thrice she conceived That has been my experience in several instances I am very old fashioned, quite as much so as Emmet, in efforts at correcting displacements of the uterus by old fashioned simple methods I am not willing to admit for a moment that Hodge, Smith, Hewitt, Gaillard Thomas and others of the old school of gynecologists were fools and false in their statements when they told us they used pessaries successfully Many of these displacements of the uterus can be relieved by the application of suitable pessaries While I have the reputation of cutting almost everything, I want to take this opportunity of correcting that error The character of suture material that we should use in our surgical work is very important I have removed great quantities of it Two or three days before leaving home I removed ligature material for three consecutive days from one patient This was a doctor's wife who had suffered the tortures of the damned for some days, and I found her uterus held down with guy ropes that Dewey ought to have to tow some of his monarchs with (Laughter and applause) I have released more ventrofixations than I have ever done I have been repeatedly told by husbands that their wives got out of bed every half hour or so for a year or more, but by putting them to bed, freeing the uterus, omentum and bladder, and possibly removing a dead ligature they have gotten along nicely

In all fairness to Dr, Goffe, I wish to say that his paper is a scientific one and the fixation of the uterus in the anterior vault is one that in all probability will give less post operative annoyance and sequelæ than others that have been so long practiced The criticism offered with regard to the ease of the operation are like those of vaginal hysterectomy It was a long time before physicians recognized that vaginal hysterectomy was an easy operation It was really unfortunate they discovered it was an easy one, and yet it has taken the profession many years to recognize that fact

Dr GOFFE (closing the discussion)—I have very few remarks to make A great many points have been suggested with which I do not agree, and while I should be glad to answer them in detail, I am afraid it would take too much time of the Section to do so We are all agreed that a simple retroversion of the uterus is not so serious a condition as to require an elaborate surgical procedure for its relief I believe we agreed, too, upon the point that it is only in certain selected cases that we advise patients who suffer in this way to undergo operation As to the use of pessaries, my experience is that when a pessary is properly applied promptly after confinement, while involution is going on, the ligaments recover themselves sufficiently to retain the uterus in place But in chronic cases of retroversion and retroflexion pessaries only afford temporary relief Shortly after removing the pessary the condition is reproduced That has been my experience, as well as the experience of men of wide observation If we carefully look into the literature of the subject we will find that it is the experience of men who have kept watch of their cases most carefully, that only about 5 per cent of them that submit to pessaries are cured

We all agree that in these cases the indications for operation are to be found in diseases of the appendages Granting that is so, to reach the appendages we must open into the pelvic cavity, and the question resolves itself into the abdominal or vaginal route of entrance, and that is a question, I believe, that is going to be fought out in the next few years, and I believe the consensus of opinion to be in favor of the vaginal route My own opinion at the present time is, and my own conduct in these cases, is never to do a laparotomy if I can avoid it If I can in any way relieve a patient by vaginal incision instead of a laparotomy I always do it I believe this is going to be the practice of the future With regard to the length of time it is necessary to retain the uterus in an anteverted position in order to recover itself, and why it recovers itself I believe that if we can retain the uterus in an anteverted position for a certain length of time by something that does not impinge upon the utero sacral ligaments as a pessary does, we allow the utero sacral ligaments to recover themselves, to regain tonicity, the muscular tissue contracts, and as the utero sacral ligaments recover themselves the uterus is retained permanently in place The slight adhesions to the peritoneal membrane do not take the weight off the uterus they do not overcome intra abdominal pressure but simply direct the axis of the uterus, and we have done that in its proper channel, as indicated upon the board We have intra abdominal pressure carrying intra abdominal pressure forward

In regard to the priority of the operation, I do not claim priority for this procedure Wertheim of Germany has suggested it and practiced it, but before he published his paper, and before Dr Byford published his paper, grounded on the same idea, I did my first operation, and while Wertheim has priority for publication in Germany, and Byford priority for publication in this country, about which I do not care, I am certainly entitled to priority for having done the operation in this country before it was published It is my wish to bring this operation before the profession more pronouncedly than it has been done heretofore, with the hope of inducing some of you to adopt it I shall do the operation tomorrow morning at 7 30 at the County Hospital in this city I do not know how serious the operation may be, but it is a case which has been saved for a few days with the idea of doing an Alexander operation I shall be glad to demonstrate to you the facility, ease or difficulty with which the operation can be done I do not claim it is a simple operation It is one that takes time and patience, but the results of the operation through the vagina are so satisfactory that I can highly recommend this procedure

---

Police Reports —The recent Latin American Scientific Congress at Buenos Ayres passed a resolution urging the daily press to refrain from publishing police reports as " there is overwhelming evidence to show that they are direct incentives to ever-widening circles of suicide and crime "

DESCENSUS AND SUSPENSION OF OVARIES

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7 10 1898

BY A GOLDSPOHN, M D ,
Professor of Gynecology Chicago Post Graduate Medical School Senior Gynecologist to the German Hospital Attending Gynecologist to the Post Graduate and Charity Hospitals
CHICAGO

The medical profession has during the last two decades been more especially interested in the *exciting causes* of disease, the infections, and the ravages of these microbic invasions The transcending value of the conquests in this direction amply explained and justified this tendency But we are finding out that the infections, after all, are generally playing only a part, and, in some cases, a small part, in the aggregate causation of many diseases We recall the tenets of our fathers who spoke of *predisposing causes* and find that these are just as prevalent in our day Within the female pelvis and abdomen these causes are created mostly by displacements of the internal generative organs, with the consequent embarrassment of their circulation and impaired trophic conditions As pertaining to the uterus, this fact has been recognized for a long time by the majority of gynecologists and general practitioners, and it explains the modern operative zeal for the cure of uterine displacements that is noble in its purpose, but very unfortunate in the choice of some unnatural methods (vagino and ventrofixation or suspension) But, that descensus (badly called prolapse) of ovaries is a positive and potent pathologic factor, that it constitutes a large part of the aggregated evils in cases of retroversion of the uterus, that it justly demands permanent correction by suspension of each ovary so affected approximately in its normal position in conjunction with every surgical invasion of the pelvis that makes it possible and that, in the presence of such displaced ovaries, entrances to the pelvis for other causes should be so chosen as to make it possible to discharge this duty toward the adnexæ also—these are facts that need to be insisted upon and reiterated, not merely for general practitioners, but also for the majority of gynecologists

The normal location of the ovary in the living woman was ascertained by Bernhardt S Schulze,[1] the father of bimanual palpation, the one only searchlight in ordinary gynecologic diagnosis, and the clinical views of this ideal gynecologist were subsequently substantially confirmed by the anatomists Hasse,[2] Kölliker,[3] His,[4] Waldeyer[5] and Vallin[6] During more recent years this topic has been invested with more practical interest than ever before, and it has been the subject of extended anatomic investigation, more especially by Aug Martin and Dr Hammerschlag,[8] a student of Waldeyer Minor differences of opinion still exist between the opinions of some investigators as to the exact location of the ovary, but they relate only to unimportant features, as, for instance, does the ovary lie more upon the anterior or the posterior part of the lateral wall of the true pelvis? Does it lie in a fossa, either specially designed for it, or resulting from indentation? But they agree in all important points—that the ovary lies against the lateral wall of the true pelvis, a little beneath its brim, and is sheltered by the tube and its mesentery (ala vespertilionis) arching over it It rests approximately in the obturator fossa (Waldeyer), being suspended against the lateral wall of the pelvis, with its long diameter parallel to that of the body in erect posture, by means of the suspensory (spermatic) ligament attached to its upper pole, the ligamentum ovarii proprium connecting its lower pole with the corresponding cornu of the uterus, and by its hilum a sesile insertion of its straighter edge into a projecting niche upon the outer part of the upper surface of the broad ligament. Its free border, which is thicker and more rounded, is directed in an inward and posterior direction. While we are compelled here to omit extended details of anatomy, we note, however, two very important practical facts, 1, that the ovary is suspended within the true pelvis, nearly as high on either side, and nearly as far away from its median line as possible, and 2, that it will be acted upon by intra abdominal pressure chiefly in a centrifugal direction, tending to support rather than to dislocate it.

Nature of descensus.—There are two degrees or stages of descensus ovariorum. In the first degree the ovary is arrested in its descent by the sacro uterine fold or ligament of the same side, and lies against the side of the supra vaginal portion of the cervix and body of the uterus, in what Waldeyer calls the fovia retro ovarica, and what Coe[9] and others call the retro-ovarian shelf. In this location it is readily felt by the vaginal finger in the posterior fornix of the vagina in bimanual palpation. In the second degree the ovary has passed over the sacro-uterine fold and then descends to the extreme bottom of Douglas' cul-de sac, where the finger in simple vaginal palpation meets it at once, almost before coming in contact with the cervix. While both ovaries are not infrequently decended to the first degree, particularly when associated with an old and extreme reversion of the uterus, it is rare that both of them lie together in the bottom of the cul de sac. Probably on account of the sigmoid flexure, the left ovary is the one which descends by far the most frequently in both stages, and it is usually the one found in extreme descensus (or prolapse). In 77 cases of ovarian descensus Munde[10] found the left one alone displaced 46 times, the right 19 times, and both together 12 times.

Causes.—Aside from various upward, inward or backward displacements which the ovary experiences from neoplasms arising from the uterus or the broad ligament, it undergoes a downward displacement—which is here alone considered—from three different classes of causes.

1 Those which occasion an abnormal or disproportionate increase in its weight, as *a*, inflammatory processes due to direct local infection or to systemic infectious diseases, especially typhoid and scarlet fever, variola and influenza, *b*, multiple cystic degeneration of Graafian follicles and corpora lutea.

2 Relaxation of the ligamentary supports of the ovary, *a*, by enfeebling or wasting diseases (occasioned partly, perhaps, by the associated loss of fat from the tissues), *b*, subinvolution during the puerperal state, after they have undergone a physiologic and somewhat proportional elongation during gestation, *c*, elongation of its ligaments, particularly of the lateral or upper suspensory ligament, by vicious traction made upon them during conservative surgical work upon the tube or ovary through an opening into the peritoneal cavity, that does not admit of sufficient access to the lateral wall of the pelvis. This is the case sometimes when a very small median ventral incision is made in corpulent women and it is always so in any form of vaginal celiotomy (Sanger),[11] which is an eligible operation for extirpation of adnexæ, but not for conservative work upon them, because their displacement—which in many cases led to their diseased condition—is not remedied, but aggravated by it.

3 Finally and chiefly, retroversion and retroversioflexion of the uterus are responsible for downward and inward displacement of ovaries, more than all other causes put together. The statement of H. T. Hanks[12] that 33 per cent of all cases of such uterine displacement are accompanied by a descensus of one or both ovaries to at least the first degree, is a very moderate one. And the fact that they are not so displaced already in every case of retrodeviation of the long uterine axis does not argue for the innocence of the latter, because descensus of ovaries associated with a normally anteverted uterus occurs in only about 2 per cent of cases that are not influenced by pelvic neoplasms or tubal swellings of any kind. It could not be otherwise, as the anatomy of the parts indicates. The utero ovarian ligament (lig. ovar. proprium) is a firm, round, comparatively unyielding, fibro muscular cord (Luschka)[13] enveloped by peritoneum and only 2.6 cm long. The other supports of the ovary, the hilum and the upper suspensory ligament, are little more than duplicatures of peritoneum containing areolar connective tissue, but practically no fibrous or muscular elements, and are therefore very yielding in character. They allow the ovary to ascend in the abdomen, with the fundus uteri during gestation, and to follow it at close range in all its voluntary or forced excursions in the pelvis.

Harmful factors incident to descensus.—These are, first partial venous stasis, and second, mechanical traumata.

1 As the ovary descends its venous current is obstructed by traction and torsion exercised upon its hilum, for the displacement occurs not merely by a sliding movement, but by a tipping over or rolling inward and downward (Sanger).

2 *Traumata from the uterus and rectum.* Although intra abdominal pressure is everywhere equal and therefore affects all intra-peritoneal bodies from all sides alike, nevertheless, during coughing, sneezing, vomiting, and other straining efforts, as at defecation, there is a marked temporary and physiologic recession of abdominal viscera into the pelvis, that occurs by virtue of proportionally greater power vested notably in the diaphragm and other muscles in the upper part of the abdominal parietes. The consequent reduction in lumen of the abdominal cavity and temporary downard recession of its viscera is the domineering feature of intra-abdominal pressure in the pelvis. It is the sovereign factor in emptying the rectum, it is the greatest force exercised in the second stage of labor, it sustains the uterus in normal anteversion or holds it in constant retroversion acccording as it is guided forward sufficiently or not by its ligaments, and woe to the sensitive feminine testicle when it departs from its sheltered nook upon the side of the pelvis and approaches the median line of the pelvic canal where intra-abdominal pressure in this manner will be brought to bear upon it, through the medium of the rectum posteriorly, and the uterus anteriorly. The traumata thus inflicted upon the descended ovary are intensified when the body of the uterus lies retroverted, which is the case in probably 95 per cent of

all cases of descensus ovariorum In complete descensus at the bottom of the posterior cul-de-sac, the ovary lies as in a vise that acts irregularly, but very frequently Every forcible exercise of intra-abdominal pressure crowds the (usually retroverted) uterus down upon it from above Every filling of the sigmoid and passage by the rectum brings contusions from behind or below, and normal coitus is scarcely possible without bruising the usually hyperemic, edematous or inflamed ovary and causing much pain When the ovary has descended only to the first degree, and lies backward and to the side of the uterus in the sulcus created by the sacro uterine ligament or fold, it does not experience the traumata mentioned so directly and invariably, but like a floating body in the knee-joint, it may be caught at any time and is compressed frequently and violently enough (Goodell)[14] to carry it beyond the domain of conservative treatment, unless it be restored to normal position permanently—with resection when necessary—before a number of years elapse

The pathologic changes that occur in such ovaries in consequence of the constant venous hyperemia and innumerable traumata are 1, hematomata in Graafian follicles and corpora lutea, 2, edema, 3, connective tissue hyperplasia, which is well known to result from constant embarrassment of the venous current, in other organs of the body, 4, chronic oophoritis, leading to multiple cystic follicular degeneration, usually in parts of an ovary, and cirrhotic conditions in other parts, 5, even perioöphoritis and eventually peritoneal fixation may occur without infection, according to Sanger[15]

It is often impossible but likewise non essential, to determine whether descensus of an ovary, in a given case, is the cause or the result of an inflammation or degeneration of the organ For, while it may be the ntire source of disorder in the former case, in the tter it imposes insurmountable barriers to all natural orces in their efforts to establish a restitutio ad integrum

The indication to permanently reduce such dislocation of ovaries is therefore general, and it should be done by non surgical means when possible, and with surgical measures when necessary, especially when resection of them is also required That ovaries so displaced, diseased, and distressing to their bearers, can by such treatment, be restored to good or relative health anatomically and functionally and, in the great majority of cases, do not require extirpation, my experience during the past five years has abundantly proven in several hundred cases Naturally the prospect or advisability of saving these organs becomes constantly less the longer the vices incident to the displacement have acted upon them and have induced greater anatomic changes They are also much less in those comparatively rare cases where their descensus occurred in connection with a normally anteverted uterus

So-called medical treatment for this disorder is really effective for a few cases in that category only in which the descensus (prolapse) of the ovary is associated with a retroversion of the uterus, namely, in recent cases of this kind, following within a month or two after parturition, in which subinvolution is a prominent factor If involution of the uterus and of the uterine and ovarian ligaments be promoted in these cases by an early restoration and retention of the retroverted uterus and descended ovaries in normal position by a properly fitting pessary, and if this be supplemented possibly with a vagino-abdominal faradic current of not more than sixty interruptions to the minute, or by massage of the uterus in anteversion, and by tonic medical treatment, then a cure of the displacement of both uterus and ovaries is here sometimes attained In non-puerperal cases, however, usually only temporary relief is obtained by these means In cases that are associated with a retroverted uterus that can not be brought into thorough anteversion by bimanual manipulation preferably—owing to peritoneal adhesions or infiltration in its supports—so that this invariable and absolute preliminary requirement for the use of any pessary can not be fulfilled, all local medical treatment resolves itself, among other minor agents, into the abstraction of water from the parts by from one to two ounces of glycerin (with bichlorid of mercury, 1 to 4000), applied by means of tampons of elastic (non-absorbent) sterilized cotton or wool These are best applied when the patient is in the genu-pectoral position, and the cervix has been drawn or crowded into the sacral hollow They may be left in forty eight to sixty hours, and should be renewed in a day or two If no septic elements linger in the adnexæ, the tenderness may hereby be so much reduced that bimanual massage may liberate the organs and right their position so that a pessary becomes a possibility, but also a life-long necessity But the only really effective treatment for descended (or prolapsed) ovaries, with given exceptions, is essentially of a surgical nature And, while this subject eminently deserves the careful attention of all general practitioners and medical specialists, because it furnishes an anatomic reason for many a persistent dyspepsia, vaso-motor disturbance or neuralgia, still I would address myself chiefly to those who have occasion and facilities for working in the pelvic peritoneal cavity, I would call their attention to the important duty, namely, in every instance before closing this cavity, to see to it that the uterus and every ovary that is allowed to remain, is also given the most favorable opportunity to remain healthy, by securing each organ as nearly as possible in its normal position or environments by dealing with natural structures in a manner that does not disarrange the normal anatomy or disturb the physiology of these or other adjacent organs Furthermore, I would remind them of the fact that with surgical methods that are designed to rectify displacements of the uterus alone merely, we are discharging but little more than half of our duty in many cases, that a nearly equal obligation frequently obtains with reference to the adnexæ, to relieve them of diseased portions (resection), or of incipient disordered conditions (salpingostomy) and to secure them in a normal location Certainly the restoration of the displaced uterus is a most potent and unavoidable means for the replacement and retention of descended ovaries, but it is not the only or all sufficient means in the majority of cases But a choice of a surgical method for the most frequently associated retro deviation of the fundus uteri is necessary for the relief of a descended ovary Vagino fixation, ventrofixation and ventrosuspension being intrinsically very unnatural and unsurgical procedures, and giving rise to disorders in gestation and obstructions in labor on the one hand, and intestinal obstruction on the other, are not eligible as normal procedures in women who retain a capacity for conception Nor are they adapted to serve harmoniously with other surgical acts that are demanded by descensus of adnexæ

The most nearly ideal structures to deal with to meet the combined requirements of a retroverted uterus and descended ovaries, with certain exceptions, are the round ligaments of the uterus These ligaments may be dealt with by three different routes 1 *By vaginal section*, by which they may be shortened intra-abdominally or may be drawn out and fastened to the vaginal wound This route is, however, only suitable in cases where no conservation work upon the ovaries or tubes is needed, so that they do not need to be drawn into the vaginal wound, away from their more lateral location, and then dropped into an abnormal situation 2 *Ventral celiotomy* This is the proper route to deal with descended ovaries, with or without an associated retrodeviation of the fundus uteri, in all cases that are complicated, not merely by adhesions, but probably also by lingering actively septic elements After removing all depots of the latter, and thoroughly liberating all remaining parts, the uterus should be secured in normal anteversion when necessary by intra-abdominal shortening of the round ligaments, every remaining dislocated ovary should be suspended in the following manner A full-curved cambric needle armed with fine silk, suitable for intestinal work, is passed through the web that connects the abdominal ostium of the tube with the ovary—called the ovarian fimbria—about midway between the two, and so as to grasp from one-half to one cm of its free edge The needle is next made to grasp a similar amount of the inner free border of the spermatic or proper suspensory ligament of the ovary near the ilio pectineal line Usually two stitches, about a cm apart, are so placed and tied In passing the needle through the spermatic ligament, it is usually well to draw out its free border with a forceps so as to avoid puncturing veins that are very prevalent in it Thus the ovary and infundibulum of the tube are both suspended mediately in approximately normal relation to each other and without direct fixation of either, leaving to each a range of mobility 3 By way of the *inguinal canals* and *dilated internal inguinal rings* This is the most nearly ideal route by which to shorten the round ligaments of the uterus, and gives the least objectionable and most enduring results in permanently correcting the displacements for which it is intended, if properly performed It is therefore desirable to treat as many cases by this modified and improved method of Alexander as possible, and, indeed, it is very serviceable, not merely for uncomplicated freely movable retro-displacements of the fundus uteri and descended adnexæ, but also for that large class of such displacements in which the formerly active septic or infectious factors have died out, but have left behind an array of adhesions about these organs and various removable deformations and degenerated portions of adnexæ This very important work can be done by this route efficiently and safely, both as to primary and sequent developments, by cutting only skin, fat, and sometimes peritoneum and separating all other tissues about the inguinal canal bluntly, by stretching the internal inguinal ring (which in every case must be opened to admit of a proper shortening of almost every round ligament) enough to admit an index finger, and by introducing this finger, and if necessary the next one also through this opening, freeing the uterus and adnexæ of all adhesions or fixations and bringing the tube and ovary up into and out of the wound where salpingostomy, destruction of cystic follicles or resection of the ovary, and suspension of it, can be done singly or collectively as required, or the tube and ovary may be taken out if worthless The internal inguinal ring is situated on a line nearly anterior to the lateral and upper suspensory ligament of these organs Therefore, the farther or the more readily the upper pole of the ovary is drawn out the greater is the relaxation of its upper suspensory ligament, and the clearer is the indication as well as the possibility of shortening it In this operation this is done by passing fine silk sutures around the ovarian fimbria, as above stated, and uniting this to the inner edge of the spermatic ligament well drawn out, at a point as low down in the wound as can be reached by depressing the surrounding abdominal wall

This not very easy, but very innocent, and extremely benign work on the patients I have gradually developed since Sept 18, 1893, when for the first time I failed to find a round ligament in performing an Alexander operation upon a mentally deranged patient who would not admit of careful previous examination Instead of giving it up, which I have never done, I opened up the wound into the abdomen and traced the round ligament from the uterus outward Incidentally, I discovered a menacing tube and ovary and removed them, obtaining a good recovery of the patient mentally and physically During the last seventeen months I have performed this extended Alexander operation thirty-six times, eleven times the simple operation was done with no intraperitoneal work upon the adnexæ aside from exploring them in each case on one or both sides with a finger introduced through the ring, and suspending one ovary in a few of the cases, thirteen times with resection of one or both ovaries, making a suspension of the latter in about half the number of ovaries dealt with, and restoring the canal of the tube in a smaller number In twelve, or one third of the cases, I removed the appendages of one side, and in some of these resected and suspended those of the opposite side In an experience with about one hundred and forty cases, the Alexander operation, variously modified, has not only not been responsible for any death, nor followed by hernia or any other evil sequel, but the general average of morbidity during convalescence is much lower than of abdominal sections proper in which only the same amount of work has been done upon the same organs, but much more incidental exposure and manipulation of intestines especially was necessary The general average of good health during subsequent years in cases of such displacements that were surgically treated upon this plan either intra abdominally or by way of the inguinal canals, so that not the uterus only but the ovaries also were secured in normal position is much better than of similar cases in which the uterus *alone* was formerly attended to by the same and other less eligible methods

FURTHER EXPERIENCES IN THE MANAGEMENT OF UTERINE DISPLACEMENTS

Presented to the Section of Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY AUGUSTUS P CLARKE, A M, M D
CAMBRIDGE, MASS

I have been prompted to present this subject on account of the misapprehension which, I believe, has prevailed respecting the character of an abnormal position of the uterus, and the method of treatment that should be adopted for the correction in certain cases

It has been a frequent occurrence to meet with cases having a marked backward displacement where a pessary had been inserted and worn for a considerable period without an attempt being made to overcome the adhesions and to restore the organ to a position as nearly normal as possible

For convenience in treatment, uterine displacement may properly be divided into two classes, namely anterior and posterior rotation

I have often found the former division to yield quite readily to dilatation and to the maintaining of the patency of the cervical canal, this can be effected by the employment of a glass drainage tube while the patient is kept in a recumbent position In those cases in which there is much congestion or inflammation of the uterine canal or of the tissues connected with the appendages, douches or other local applications should be used previous to dilatation and drainage

Of the two results that follow anterior displacement, I have noticed that sterility has been the more common condition or has not been as easy to control as has dysmenorrhea

Within the past year I have observed an unusual number of cases of sterility dependent on a preternatural closure of the uterine cervical canal In one case my records show that the patient had some eight years before given birth to a child the anteflexion of the corpus uteri was of the third stage, or of an angle about forty degrees In endeavoring to effect dilatation I found that there existed much hyperplasia of the cervix, which was evidently the result of an old endometritis An innocent looking exudation taken from the cervix, when placed under the microscope, revealed the presence of gonococci, the existence of which must have been of long standing and must have contributed to the sterility and to the changes that had taken place in the endometrium Dilatation of the canal, incision of the interior of its cervical portion, curettement, drainage and cauterization with a 60 per cent solution of chlorid of zinc finally overcame the dysmenorrhea and relieved the essential symptoms

In some instances I have found that anteflexion resulted undoubtedly from congenital causes In very marked or aggravated cases I have observed vesical symptoms to arise The urine may contain a muco purulent sediment After dilatation and other local measures have been tried, a properly fitted Hodge pessary, introduced so as to lift the uterine fundus from the bladder, afforded satisfactory relief

As regards anteversion, I have found that condition often associated with subinvolution and therefore has been the result of pregnancy and of parturition, laceration of the cervix, and relaxation or inflammation of the uterine ligaments Dilatation, curettement, and the direct application of iodin and of other alterative agents have proved excellent preliminary measures of treatment The laceration of the cervix and of the perineum and also of other parts should in due time be attended to

In two cases of anteflexion of the third degree, pregnancy took place before opportunity for a systematic plan of treatment could be carried out In one of the cases vomiting of pregnancy occurring after the tenth week became alarming, this, however, was brought under control by rest and by tamponading the vagina so as to elevate the uterus from the rectal, sacral, and vesical tissues Such vomiting can often be relieved by the milder means used for replacement of the uterus If, however, there are firm adhesions, as there were in a case to which I was called some months since little can be safely attempted in this respect until after the term of pregnancy has been completed

It is sometimes said that the stimulating effect of pregnancy tends to improve the development of the uterus and thus to overcome the anteflexion In one of my patients, notwithstanding pregnancy went twice to full term, the anteflexion recurred soon after each parturient process had taken place

As before remarked, I have relied in the treatment of anteflexion much upon resort to dilatation, either by the gradual or by the rapid method, as the condition of the case would seem to justify In regard to the time when rapid or more forcible dilatation should be attempted, much will depend upon the character of the case If there is evidence of much old hyperplasia, with a preternaturally small cervical canal, dilatation should be had recourse to as soon after menstruation as it will be deemed expedient to undertake If, however, the cervix is soft and imperfect in its size and shape and there is a tendency to menorrhagia or metrorrhagia, the operation should not be performed for some days after the flow has ceased

In dilating the uterus I have noticed that much care should be taken not to exercise too much force in the beginning, the condition of the tissues somewhat above the internal os should not be overlooked In cases in which there is considerable hyperplasia or induration of cervical tissue, incision of the parts within the canal will be most helpful, the sudden forcible stretching of the tissues without incision is liable to be followed with delay in recovery or with other untoward results In cases in which there is a complication of salpingitis, ovaritis, or other inflammatory processes, rest and preliminary treatment should be tried before the more radical measures are employed

In all cases, after dilatation has been effected, the patient should be kept for a considerable period in the horizontal posture If sterility or dysmenorrhea continue, dilatation, curettement and intra uterine applications should be repeated at proper intervals I have found, however, that when treatment was seasonably undertaken, favorable results in a large percentage of cases were early achieved

In the management of retroflexion we have been accustomed to speak of the corpus of the uterus as being bent or turned backward from its original position. In this connection it might be proper to say that the cervix of the uterus is in its normal position when its axis is nearly at right angles to the axis of the vagina and the corpus inclined forward toward the abdominal wall. The degree of retroflexion may then be determined by finding the measurement of the angle that is formed by the backward displacement of the body from the internal os. We may have a retroflexion that embraces an angle varying from the dimensions of half a circle to those that are included in less than a quarter of an arc. As regards the treatment of such cases many points have to be considered. Of course, replacement of the organ must first be accomplished and its reduction must be maintained. I will not discuss the question of repair of the lacerated cervix or of an injured perineum, for we all now recognize that such cases should receive proper attention, as well as that measures should be instituted to overcome the condition of subinvolution. The cases that of late have given the most trouble have been those in which the organ was firmly bound down by adhesions, or after the adhesions have been overcome, the ligaments and other parts have been found so weakened and relaxed as to fail to act as guys in sustaining the organ in its restored position.

As we come to appreciate more and more the influence of intra-abdominal pressure in the maintaining of the uterus in its normal position, we shall perceive more clearly the reason why we have succeeded in some cases by a resort to a special method of procedure, while in other cases such operations have proved to be almost entirely useless.

Last winter there came under my care a case in which Alexander's operation had been tried some three months previously without any beneficial results being apparent. I found, on further examination, that the retroflexion was of nearly the third degree. Some dysmenorrhea was complained of, besides the effects of pelvic pressure and other annoying symptoms, the result of reflex irritation. The vulvo vaginal introitus was relaxed and patulous. The only operation that I could recommend was Hegar's method of posterior colporrhaphy. The posterior vaginal wall was narrowed so as to overcome the patency of the vulval opening, and thus to prevent the ready ingress of air. The uterus was then kept in place by a properly fitted Hodge pessary, though the round ligaments were much relaxed, and no attempt was made to reshorten them.

I believe that Alexander's operation is the most useful in those cases in which the vulvo-vaginal wall is so intact as to be sufficient to maintain the intra-abdominal pressure. There can be no doubt that had the perineal and vaginal tissue been repaired at the same time that the operation was undertaken for shortening the ligamenta rotunda, the results, in all respects, would have been typical of the benefits that could have been achieved by necessary operative interference.

Those cases in which the uterus is displaced backward and is firmly adherent, are frequently the most troublesome to manage. Manual and instrumental interference may sometimes be helpful in effecting the proper reduction, so, also, will repeated tamponading with iodoform gauze or with prepared lamb's wool but these procedures have many times proved to be tedious measures of treatment. In such cases, Alexander's operation will have to be deferred, this operation would be especially contra-indicated if the adnexa were prolapsed and adherent also. The course then to be pursued will depend on the amount of suffering.

If the severity of the symptoms cannot be relieved by resort to milder means, or by the recourse to the extra-peritoneal method, ventrofixation or ventrosuspension may, of course, be the next expedient. Before resorting to this measure of proceeding it is highly necessary to be certain, as it is in Alexander's operation that the perineum and vulvo-vaginal tissues are intact, and that there exists in those parts no patency that would materially overcome the equipoise of the intra-abdominal pressure.

On making an abdominal incision other factors as contributing causes of the retro displacement may be discovered, these will have to be dealt with as may, in each individual case, seem proper. Ventrofixation as a routine method of treatment for correcting retro-displacement of the uterus can, according to the present knowledge of the results of abdominal surgery, be scarcely approved. The operation in certain cases has its peculiar benefits, in others it has its exceeding limitations. Ventrofixation or ventrosuspension, I have found, is an admirable surgical expedient in those cases in which one or both of the appendages or portions of the broad ligament have been removed through an abdominal incision, for overcoming retro-displacement in married women, I believe that it is best that the operation should, if possible, be deferred until the approach of the menopause. If conditions admit of a choice, Alexander's operation for shortening the round ligaments in properly selected cases is no doubt the less dangerous to the patient's life and the less likely to interfere with the normal evolution of pregnancy, though I have seen a few cases in which utero gestation, taking place at an early date after the operation, terminated about the sixth month in premature parturition.

DISCUSSION ON PAPERS OF DRS. GOLDSPOHN AND CLARKE.

DR. JOSEPH EASTMAN, Indianapolis—I desire to thank Dr. Goldspohn for his excellent paper. I endorse every word I heard, although I did not enter the room until the paper had been well begun and the foundation had been laid. The paper certainly shows that the Doctor is studying along anatomic lines in a conservative way, and with the absolute view of effecting cures, and not for the sake of making new experiments or developing new modes of operating.

DR. HOWARD A. KELLY, Baltimore—Some of you may recall a paper in the *British Gyneological Journal* in 1889 with reference to stitching up the ovary with its attendant prolapse. I myself have never felt perfectly clear as to the pathologic significance of those ovaries that were felt with unusual distinctness in Douglas' pouch, and I have never felt warranted in opening the abdomen for the sake of stitching up such ovaries. When I have opened the abdomen for other causes these ovaries have never appeared to be diseased, they may have had small cysts in them. I shall watch with interest the effects of operations upon descended prolapsed, more or less tender ovaries. In the course of abdominal operations, where I have removed the tubes, and the ovaries have tended to drop back, I have pinned them to the cornu of the uterus in a number of instances. It is interesting to note the varieties or differences we find in the course of operation in the utero ovarian ligaments. Of course, the length of the ligament allows the ovary to drop back. I have seen a case within the last two weeks in which the ligament was over two inches in length. That was in association with a tumor, which was large. When the ligament was pulled out I never saw one as long before. I have seen them short and thick. I wish to say in this connection, that a short time before I came here I saw a case where there was absolutely no utero ovarian ligament. The appearance was curious. In opening the abdomen and exposing the uterus, saying this *à posteriori*, the ovary was plastered right on to the uterus on both sides for about two thirds of its surface, the scar tissue looking like skin that had been in water for some time, radiating several centimeters around This was the only case in which there was absence of the utero ovarian ligament

Dr **William H Humiston**, Cleveland—In reference to cases of prolapsed ovaries, I find it is a great question for me to decide as to the necessity for an operation I do not feel clear in deciding to operate until I have gone through a course of treatment in these cases It is rare for me to find an ovary prolapsed unless we have descensus or a retroposition of the uterus In those cases I find that the history gives an indication as to what the result may be from ordinary treatment If the case has existed for a long time, usually it has failed to be permanently benefited by putting the uterus in its proper position and condition But I feel like trying the conservative method always in doubtful cases before resorting to surgical procedures I find in a great many of these cases, if the symptoms have been only a year in duration, that they do get well by placing the uterus in its proper position and supporting it there with rest in bed, hot water douches, by glycerin pads, and with medicated boro glycerid, or ichthyol glycerin solution I have never done the operation of suspending the ovaries, for after failure of the conservative method of treatment, the symptoms not being relieved to any extent, upon opening the abdomen and inspecting the appendages I find them in a pathologic condition, and then removal of them is the only thing to give permanent relief, and in those cases I have had most pronounced success Many cases that have come to me with symptoms of recent date, say within a year, have been permanently cured by the ordinary treatment with pessary, after six or seven or ten weeks of support by pessary The uterus remains in its position and we have no further trouble Usually pregnancy takes place and they go on to full term without any trouble Where the appendages are not diseased, merely congested, and the ovaries prolapsed, perhaps the conservative treatment has been usually sufficient in my experience

Dr **E Gustav Zinke**, Cincinnati—I can not believe that an otherwise healthy ovary or ovaries that are prolapsed, even though they be lying behind the uterus or in front of it, will give rise to any serious symptoms—certainly any symptoms that would in my opinion justify operative interference This is the view which I take of this procedure I have yet to see a single case of prolapse of the ovaries without adhesions that has given rise to such symptoms as will warrant operative procedures, except perhaps such as a patient may be put in the genu-pectoral position several times a day for as long as she may stand it in connection with the use of tampons, keeping the organs in their place as much as possible, but when I have ound relief from measures of this kind, I always feel sure that whatever symptoms there were present they were not the result of adhesions, and in no case were they so severe as to justify an abdominal section for the purpose of stitching the ovary in its proper place

Dr **J H W Chestnut**, Philadelphia—My experience in these cases coincides very clearly with that expressed by Dr Humiston of Ohio, and Dr Zinke The numerous cases I have seen have been so comparatively insignificant in their ulterior influences that I have not yet been called upon to operate for removal of the ovaries except where there were evidences of intrinsic disease The frequent placing of the patient in the knee breast position, the retention of the ovaries in their position by tampons medicated by glycerin and ichthyol and rest in bed with the hot douche will give relief Where there have been adhesions I have felt compelled to remove the organ I have no doubt, however, that there are cases in which this procedure will be of value

Dr **Miles F Porter** of Fort Wayne, Ind —There are certain cases of prolapse of the ovary in which we know the shortest and best method of treatment is some method of fixation or their removal With the Goldspohn method I have had no experience whatever, but I have had some happy results from abdominal fixation of the ovaries, in cases where apparently there was absolutely nothing wrong save that the ovary was out of position—*sometimes out of position* one day and in position the next A few days ago a case of this kind presented itself which had been treated by the usual method without result, and upon leaving she remarked to me that the first movement of the bowels without pain and without distress, she had *for a period of* eighteen months, she had had within three months after the ovary was put in position, and retained there through an incision in the median line

Dr **Charles I Bonfield**, Cincinnati—It seems to me that the experience of Dr Kelly and of Dr Zinke that these cases do not cause some trouble must not be the experience of the entire profession The cases that are attended with retroversion of the uterus, and the cases that are relieved when the retroversion is relieved are amenable to the office treatment so graphically described by Dr Humiston of Cleveland But when the ligaments of the ovary are so stretched that replacement of the uterus does not also replace the ovary, then it has been my experience that local treatment is very hard to carry out and it is almost impossible to make it effective A great many of the gentleman have said that the ovaries, if not diseased, need not be disturbed, but it has been my experience, after watching these cases, that if I am not able to relieve them in any way, sooner or later the ovary itself becomes diseased, the malposition of it interferes with its nutrition, and sooner or later we have a diseased ovary which requires its removal The gentleman who spoke a minute ago, from Iowa (Dr Fairchild), voiced my sentiments when he said that certain women could not afford to be treated months for this condition, such as school teachers, music teachers and clerks in stores They cannot afford to pay money for their care nor can they afford to rest long enough to get temporary relief In those cases some surgical measures are indicated

Dr **E Gustav Zinke**, Cincinnati—It is possible I have placed myself in a wrong position because I was not here when the paper was read I may not have been correctly understood with reference to what I had said before What I meant to say was that when we have a perfectly healthy ovary, in other words, no diseased condition in the pelvic cavity, only prolapse of the ovary, that the symptoms arising therefrom can not be sufficiently severe to warrant operative interference Furthermore, when I spoke of the genu pectoral position for the relief of the condition, everybody knows that there are no adhesions present The treatment need not be very protracted, and a few applications will probably be sufficient If protracted treatment becomes necessary, it is evidence that adhesions exist, and that other pathologic conditions have arisen for which operative interference will be perfectly justifiable I wish it distinctly understood that I endorse every honest effort I do not know whether Dr Goldspohn does this operation for prolapse of the ovary without any diseased condition present or not I simply make these statements in order to make myself understood I hope if I did not make myself understood then I have done so now

Dr **Joseph Price**, Philadelphia—My experience has been instructive and interesting in this line of work, although I have not resorted to surgical procedures except in the presence of pathologic conditions A prolapsed ovary with fixation commonly has occlusion with retention, and the same holds good with retrodisplacements with fixation It is exceptional to find a fixed uterus without an occlusion with retention of blood, pus or water You have alluded to the importance of surgical interference in this class of cases For simple descensus of either or both ovaries, or the truant ovary of the Germans, we have had a great variety of treatment I do not approve of the office treatment It avails but little If you are going to treat a case successfully you must put the patient at rest, and if the treatment be local and general you will succeed in many cases in giving marked relief by some of the methods recommended The globe trotters and the class of women who do not want to be mothers, or prefer postponing the treatment of their troubles for trivial purposes or other convenience, are the ones that annoy us most If you can convince some of these women that they should become mothers you will, in many cases, cure the truant ovary Before leaving home I examined a patient who has not conceived for eleven or twelve years She is living in the extreme Northwest, she was the victim of artificial methods of preventing conception, and, as a consequence, had marked nervous disturbance bordering upon insanity I found in her case, large, congested uterus and truant ovaries I put her to bed, corrected the displacement of both ovary and uterus, and she returned *eight months* later to *ascertain* the presence or absence of pregnancy I assured her that she was pregnant some four months or more She went away rejoicing We are burdened in the East by a number of cases traveling all over the world They have an unnatural dread of having a baby, and a baby is a thing we love down East above all things

Dr **Clarke** (closing the discussion on his part)—In most cases where we have displacement of the adnexa we have displacement of the uterus, and in my paper I spoke of the importance of intra abdominal pressure, and I believe we should in all cases endeavor to restore that There is a class of cases in which I think my methods of treatment should be of avail, but I have seen some cases in which ventrofixation or ventrosuspension has been undertaken *and carried out* with so little good effect, that I am afraid of it I believe if the Alexander operation is performed in a certain class of cases, and the peritoneum is intact and the subinvolution is overcome, with a little rest in bed, the woman kept in that position, we will get almost a perfect cure If we perform Alexander's operation without restoring the parts to overcome subinvolution and without watching the condition of the ovaries and tubes we will meet with failure The purpose of the round ligaments is to prevent backward displacement, and to fasten the uterus to the abdominal walls or to the peritoneum has, in my experience, been a failure in those cases in which the tubes and ovaries have been removed

Dr Goldspohn (closing the discussion)—I condemn the surgical monstrosities of ventrosuspension, ventrofixation and vaginofixation Direct or immediate fixation of the uterus to the abdominal wall, without an intervening band, is so serious a thing that soon it will be malpractice to perform it in women who may conceive Suspension exposes the patient to the risks of intestinal obstruction If the bands made by these operations were the result of anything else, the operators themselves would open the abdomen to remove them The records show that two thirds of the women subjected to these operations have troubles in gestation or labor, or both The harvest of ileus after ventrosuspension has only begun The round ligaments are merely guy ropes Intra abdominal pressure is the holding force that either supports the normally anteverted uterus or condemns the retrodisplaced uterus to remain permanently in that position The best way to correct these displacements is by means of the round ligaments and through the inguinal canals The cardinal points in the technique of Alexander's operation are that the way into the abdomen is not to be cut, but the tissues are split so that they fall together afterward, that the conservative operations upon the appendages can be done through the dilated wound, and that each layer must also be closed individually At least 95 per cent of the cases of descent of ovaries are associated with retroversion of the uterus, and hence the treatment must be directed to the displacement of both The gynecologist who knows no middle ground between amputating an ovary and doing nothing, stands in the same position as the surgeon who would amputate every diseased leg I never do Alexander's operation without curetting thoroughly and repairing the cervix or perineum, or both, at the same sitting, if at all required My technique of the operation is briefly as follows The pubic spine and Poupart's ligament are the guiding points An incision is made half an inch above the ligament, beginning near the spine, passing down to the aponeurosis of the external oblique The bunch of fat in the external ring is grasped with forceps and a finger is placed in the ring The aponeurosis is then split up without being cut, and is held aside by retractors, the round ligament is traced to the internal ring by tearing the attachment of the deeper muscles to it, when the end of Nuck's canal can be seen This is cut slightly and a pedicle forceps is introduced and the internal ring is stretched so that the index finger can be introduced With this all adhesions to the uterus and to the tube and to the ovary of the same side are severed The ovary and tube, if abnormal, are brought out, inspected and their condition is corrected surgically if possible, or they are removed The round ligament is sutured to the under surface of Poupart's ligament, in the act of closing each layer in the wound separately, and after the principle of Bassini hernia operating

---

THE TREATMENT OF AMBULATORY GYNECOLOGIC CASES

Presented to the Section of Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10

BY DENSLOW LEWIS, M D
CHICAGO ILL

Sanger tells us that gynecology is the surgery of the female genitalia His definition is neither exact nor complete, but it is clinically useful As a matter of fact the first thing to be determined in every gynecologic case is the advisability of operation A necessary subdivision of the question is at once apparent There is the consideration of immediate operation at the time of examination, the operation in such cases being trivial There is to be considered the advisability of local and systemic treatment, which is often to a great extent tentative, with the reasonable hope that surgical treatment may ultimately be dispensed with or may become relatively insignificant, at least not especially dangerous, and finally, there is the certainty that operative measures are imperative, perhaps that their immediate adoption is the only known means of relief or of saving life, in which event removal of the patient to a hospital is usually indicated There is, therefore, in the first examination of every gynecologic patient a chance for much difference of opinion, both as regards the indications for operation, the kind and extent of surgical measures to be adopted, as well as the relative value of measures, chiefly medicinal and topical in character, which include no extensive surgical interference

I desire in this connection to refer to the gynecologic cases I have seen at the Chicago Policlinic during the past four years I ask your attention exclusively to those cases, very properly designated as ambulatory, where the women, although often seriously diseased or suffering from a condition which seems to demand surgical treatment, are unable to submit to radical measures which would necessitate sojourn in a hospital or cause them to give up their daily work These patients are chiefly working women, many of them having to support children and at times a husband If not employed in some shop or factory they are obliged to attend to household duties, from which they can not absent themselves without serious interference with the routine of their family life In some instances they are impostors I have known them to come several thousand miles for treatment They have settled down in Chicago with their families and have taken advantage of our dispensary and hospital facilities in the most shamefaced manner Prostitutes are not frequent attendants of our gynecologic dispensary The women, as I have said, are, as a rule, obliged to work for a living They are often poor, but not destitute They are, most of them, trying to do their part in the struggle of life For this reason it is a hardship in several ways for them to remain in the hospital long enough to convalesce from an operation They can not indulge in the "rest cure," or in many instances, purchase proper food They seek relief from their ailments without interference with the routine of their daily life It is gratifying for me to be able to say that often such a course of treatment is practicable and sometimes surprisingly successful Let me briefly detail the methods in use in the different classes of cases I have been called upon to treat

Venereal warts if small are snipped off with scissors under cocain anesthesia Occasionally the base is touched with a drop of carbolic acid If the warts are large and extensive the patient goes to the hospital for a few days, the strip of mucous membrane from which they grow is dissected off and the edges united, very much as in a Whitehead operation for hemorrhoids During pregnancy no operation has been undertaken, nor have the warts, as far as known, in any way interfered with parturition During the puerperium they diminished in size and in some cases they have disappeared Chancroids are touched with strong carbolic acid for its anesthetic effect, followed by a drop of fuming nitric acid applied with a glass rod Powdered boracic acid is applied to suppurating surfaces after the parts have been cleansed with a boracic acid solution and dried with absorbent cotton No case of phagadena occurred Chancres were not often seen They occurred on the fourchette and inner surface of the labia majora They were dusted with boracic acid and pills of proto iodid of mercury were exhibited.

Condylomata have been dusted with powdered boracic acid or stearate or oleate of zinc. A douche often of a 1-4000 solution of bichlorid of mercury, would be given two or three times a day and general cleanliness of the parts would be insisted upon. With these local measures, under a vigorous mixed treatment, the condylomata would disappear or perceptibly diminish in size, and the ulcerative condition of the neighboring parts would improve.

Pruritus, in connection with pathologic conditions would often be relieved by applications of powdered boracic acid and the maintenance of cleanliness. In other cases a saturated solution of sulphite of sodium would be prescribed with great benefit, although in some cases of pregnancy its use would have to be persisted in.

Lacerations of the perineum would often present themselves, but usually cicatrization had taken place and no serious discomfort was occasioned by their presence. In recent cases powdered boracic acid would insure healing without much pus. Where extensive rectocele existed the patient was advised to submit to a Hegar operation in the hospital. In many instances circumstances prevented the acceptance of this advice, and it was found in the great majority of cases, that when the patient, in the course of time, recovered from pelvic pain and other symptoms due to infection of some of the pelvic viscera, the rectocele apparently caused but little inconvenience as long as the bowels acted daily. Cases of somewhat extensive laceration of the anterior vaginal wall would favor the development of a cystocele, but in many cases without appreciable inconvenience. Here also, it was noted that when the symptoms due to infection were relieved the cystocele would persist, but it would cause—at least while the patient was under observation—no decided bladder symptoms.

Many cases were observed of what is commonly called "irritation of the neck of the bladder." The symptoms were undue frequency in urination and a desire to pass a drop more accompanied by more or less pain. Urethral caruncle when observed in connection with these symptoms was promptly removed under cocain anesthesia. In addition to the routine treatment of infection of the pelvic contents, to be later described, it was customary to recommend the copious drinking of water and the exhibition of twenty grains of benzoate of sodium three or four times a day. Only exceptionally would it be necessary to give an anodyne. When pain was severe it would usually be relieved by a suppository of one-half grain of the aqueous extract of opium often combined with one-third grain of the alcoholic extract of belladonna. Once or twice a year there would be a case of chronic urethritis which would disappear under the foregoing treatment and the bi-weekly passage of steel male sounds, gradually increasing in size, as is practiced in the treatment of urethral stricture in the male. Rarely was it necessary to send the patient to the hospital for bladder irrigation, ureteral exploration or some operative procedure.

Infection of the vulvo-vaginal glands, one or both, was often observed. In many instances no special discomfort was occasioned, and in the course of time the infection would subside. In other instances pus had formed so that a free incision was necessary. Several cases were seen that had persisted for years. It was noted that a small incision, amounting to little more than a puncture, had been repeatedly made, which would allow the evacuation of pus, but the abscess would invariably recur. In such cases it was gratifying to observe that an incision which extended throughout the length of the gland would invariably effect a cure within a few days. Some chronic cases where induration was apparent were sent to the hospital and operated on by excision of the glands.

Hemorrhoids were often seen in connection with other diseased conditions. If external, and especially if situated some distance from the verge of the anus, they were incised and the clot turned out. In other cases an ointment of equal parts of ung gallæ and ung zinci benzoat, containing perhaps ten grains of extract of opium to the ounce would reduce the tumors in size and relieve the itching and irritability complained of. Of course means were adopted to secure free bowel movements in each case.

Internal hemorrhoids and anal fissure were treated by moderately stretching the sphincter muscle and applying powdered boracic acid twice a week. Of course here also free catharsis was secured. It was found that these measures were usually sufficient to heal the fissure, reduce the hemorrhoids to an appreciable extent, and to relieve all symptoms due to their presence.

Leucorrhea, as would be expected, was a symptom frequently observed. Indeed, its presence often induced the patient to apply for treatment. She would suffer also from variable pelvic pain, but in many cases the constant discharge was so disagreeable, or its continuance was regarded as such a drain on the system that immediate and permanent relief was urgently demanded. When the discharge was at all profuse or the attack was recent, the gonococcus would be looked for. A drop or two of the pus would be collected on a glass slide, methyl blue or gentian violet used as a staining material and the specimen examined microscopically. If diplococci were found Gram's iodo-iodin solution would serve to differentiate the gonococcus by decolorizing it. Usually it was found where the discharge was profuse, unless a recent infection of the endometrium or a cervical laceration was clearly demonstrable. Vaginitis was rare except in children. This was the rule in nearly all cases of leucorrhea, the delicate character of the mucous membrane apparently offsetting the protection afforded in adults by the pavement epithelium. The treatment of gonorrhea and of the vaginitis of children consisted in the application of a nitrate of silver solution to the mucous membrane of the vulva, the entire surface of the vagina, the portio vaginalis and the exposed portion of the interior of the cervix. In adults this application consisted of a 20 grain to the ounce solution, and was made with a swab of absorbent cotton at intervals of three days. A 1-4000 bichlorid douche used twice a day would also be prescribed. In children the application was necessarily less thorough. It was made in the same manner to the vulva and lower portion of the vagina, but in addition a vaginal injection of the solution, 10 grains to the ounce, would be made by means of an eye syringe.

In most of the cases that presented themselves for treatment there was evidence of infection of a cervical laceration, the endometrium, the lymphatics or veins near the uterus, the interior of the tubes, the ovaries, or the peritoneum adjacent to the fimbriated extremities. These cases constituted the conditions often called "cellulitis," "perimetritis" or "parametritis" By me these terms are no longer used They present to my mind no definite idea of the exact pathologic condition that exists nor are they in any way indicative of etiologic relationship nor suggestive of suitable means of treatment I also abstain from the use of the words "endometritis," "salpingitis" and "ovaritis" These expressions, it must be admitted, indicate very often the true condition that exists but, with our latter day knowledge of bacteriology, we understand that the inflammatory reaction that occurs when infection takes place, is the effect of microbic action and is always the result of a morbid process, which is itself usually of the first importance

I have no wish to be pedantic, at the same time I contend that for many reasons, it is preferable to say infection of the endometrium or tube, as the case may be This defines the exact condition This is a step in the right direction It will not be long before the variety of infection will be stated, with very great value to our knowledge of definite therapeusis The effects of the inflammatory reaction must also be recognized and appreciated Indeed, in many of these cases, the extent of the inflammation is of itself a positive indication for determining the proper course of treatment

Lacerations of the cervix were often noted Sometimes there would be no infection The finger could detect a solution of continuity in the portio vaginalis but no other symptoms, subjective or objective, could be determined In such cases the lacerations were let alone In other cases the infection was the factor of importance The portio vaginalis, torn bilaterally or presenting an irregularly stellate laceration, would be everted or hypertrophied, the red and inflamed surface of the endocervical mucous membrane constituting the condition which used to be called "ulceration of the womb" In all such cases there was found an extension of the infection to the endometrial mucous membrane or beyond Repair of the lacerations or amputation of the cervix, together with a thorough curetting, was usually recommended, but in most instances, sociologic and economic reasons prevented the acceptance of this advice Under these conditions, powdered boracic acid was applied and the routine treatment, soon to be described, was persisted in, usually with satisfactory result

I may as well state frankly that our diagnosis was often imperfect and incomplete in many of the cases where infection, originating in the endometrium, had extended either by continuity of epithelial surface through the tube to the ovary or to the peritoneum or where invasion occurred through veins or lymphatics—often of the placental site—to the parenchyma of the uterus or the surrounding areolar tissue It must be remembered that we encountered stout patients and those in whom there was much muscular rigidity or extreme tenderness The bimanual examination was often facilitated by the assumption of the exaggerated lithotomy position and the use of a vulcella forceps, but these means were not always sufficient to enable us to map out the pelvic contents with any degree of accuracy, and it was rarely practicable for our patients to take an anesthetic

Under these conditions the presence of infection could be noted but the locations infected could not be accurately determined until the patient had become accustomed to our examination or the tenderness had appreciably subsided As a matter of fact, as I often took occasion to say to the practitioners who attend our clinic, the etiologic relationship and the location of the infection are relatively of little consequence in comparison with the importance of knowing its extent, that is, if it has gone on to suppuration The presence of pus in the pelvis is, in my judgment the important point to be determined in the examination of gynecologic cases showing the effects of infection When pus has formed to any great extent its evacuation is usually the proper treatment In our patients, however, it was often impossible to operate and our advice had to be disregarded It is extremely gratifying to be able to say that in the great majority of cases where pus was diagnosed in the tube or the areolar tissue of the broad ligament our treatment would succeed in relieving all pain and all discomfort so that the patient became symptomatically well This experience in time modified our prognosis and had its effect upon our advice When a pyosalpinx was discovered we did not feel it necessary to demand an immediate celiotomy as the only means of saving life When pus was diagnosed in connection with the ovary or broad ligament we insisted that the surest and speediest way to ensure recovery was a vaginal incision and drainage, as Henrotin has so ably pointed out Nevertheless, we soon learned that if circumstances prevented a sojourn in the hospital and operative interference, there was a reasonable probability that in the course of time microbic action would cease, the pus, now no longer septic, would become absorbed or encapsulated, and the patient would be free from pain and discomfort We learned further that our routine treatment was beneficial in all cases of infection of the pelvic organs or the tissues surrounding them As a matter of practice, we submitted all patients of this class to essentially the same treatment We succeeded in all cases except those requiring surgical interference, and in many of these cases, when we advised vaginal or abdominal incision for the evacuation of pus, curetting for the removal of granulations or the retention of membranes following abortion or labor, trachelorrhaphy or some form of colporrhaphy, it was most surprising to notice that the symptoms would gradually subside and the patients would be able to continue their daily occupations without inconvenience

I will now state the details of what I have called our routine treatment I do not claim that it is the best treatment, much less that it is the only treatment for this class of cases In our hands it has been found convenient and many hundreds of poor women can testify as to its success I consider it worthy of mention, although there is nothing new about it, for it must be remembered that the patients who were benefited were working women unable to purchase expensive drugs, food or appliances and forced to continue on in their daily routine of life Our first direction is a 1-4000 bichlorid of mercury douche to be taken as hot as can be borne twice daily, with the patient on her back and the hips up The error is explained of an attempt to take such a douche with the bulb syringe or on the water closet seat The patient lies flat on her back in the bath tub with a rubber water bag under her hips, or, as often happens, if there is no bath tub, she lies on the edge of the bed with her feet separated, each on a chair

The bowels are made to act freely at least once a day For this purpose it is customary to prescribe the fluid extract of cascara sagrada in a routine manner. The drug is given at first in 20 drop doses to be taken three times a day. If the bowels do not move, a compound cathartic pill is given at night and a dose of salts in the morning. Sometimes it is necessary to give at first a saline enema or one of glycerine and water. However this may be, no more than 20 drops of the cascara are given at a dose. In a few days the salts may usually be omitted in the morning and some days later the pill at night is also omitted, to be promptly resumed, however, if on any day the bowels fail to move. It is usually found that, after a week's time, the three daily doses of cascara produce daily evacuations. Our directions now are that the drug be taken regularly in the same dose no matter how frequent the discharges may be, provided they are fecal in character. It is noted that after the cascara has been taken for some little time, colicky pain and diarrheal movements supervene. This is our signal, not for stopping the medicine, but for its exhibition in the same way three times a day in a smaller dose, say 15 drops instead of 20. Another period of regular bowel movement usually follows but, in the course of time there again occur watery movements and abdominal colic. Here again the dose is diminished, the original dose being promptly resumed or the cathartic pill, enema or salts given if required. In a few weeks more the dose can often be still further reduced although taken in the same regular manner, three times a day. Finally, after the dose has been reduced to one drop three times a day, the medicine can be discontinued and the bowels act freely and regularly of their own accord.

The patient is told to assume the knee-chest position twice a day for ten minutes. Twice a week, when she calls at the dispensary, she assumes this position upon the operating table, a large Sims's speculum is introduced and a tampon of absorbent wool, one end soaked in a 10 per cent solution of ichthyol in glycerine is applied by means of a uterine dressing forceps. This tampon remains in situ some twenty-four hours, unless an offensive discharge or undue irritation ensue, and is removed by the patient by means of a string which is tied to one end of the tampon.

This is our routine treatment of infection of the pelvic contents. Powdered boracic acid is dusted on the inflamed cervix. Benzoate of sodium is given as already stated when there is irritation of the bladder. Quinia, iron and strychnia are often given with phosphoric acid. Some form of pepsin with hydrochloric acid is prescribed when there is stomachic indigestion. These drugs are invariably combined with cascara even when the patient disclaims any tendency to constipation. Very rarely is it necessary to prescribe anything else. No uterine probe or sound is used in my clinic nor is there ever made a uterine application. Our experience with pessaries has consisted solely in their removal. No uterine dilatation is practiced. I hardly need say much in explanation of this plan of treatment. My purpose is to record facts and not to attempt to defend a theory. Uterine dilatation is rarely, in my opinion, a justifiable procedure in an ambulatory patient. In the class of cases under consideration it would have been a dangerous experiment. For the same reason no application was made to the endometrium. My experience with hundreds of women during the past four years appears to show that it is unnecessary.

Some surprise may be occasioned by the absence of all reference to uterine displacements. It does not mean that they were not observed. They were usually found, however, in connection with pathologic conditions which were themselves of chief importance. In the absence of fibromata of the uterus or cysts of the ovary or broad ligament, in the absence of ectopic gestation, hematoma or other condition which mechanically influenced the position of the uterus, displacement occurred as the sequel of infection or the inflammatory action that had ensued. With an infected puerperal uterus, with adhesions which matted the parts together, it was evident that the infection was of the first importance, and it was usually found that when the infection was benefited by treatment, the uterine displacement disappeared or caused no inconvenience unless there were present conditions warranting operation. For this reason the displacement of the infected uterus was practically disregarded. The mobility of the healthy uterus was explained to our practitioner students by reference to well-known facts concerning the anatomy of the parts and by demonstration in patients free from infection. The presence of infection was pointed out both in reference to its etiologic relationship to the displacement and its importance as an object of attack in our treatment. The symptoms complained of were very much alike wherever there was infection which had extended much. There was pelvic pain and a "bearing down" sensation, usually increased during menstruation. There were often bladder symptoms, due to pressure, or to an amount of infection which showed itself by no objective symptoms. There was lumbo sacral, as well as inguinal pain, and there was often pain extending down the inner surfaces of the legs. There were reflex symptoms in great number and in varied character. It was our constant endeavor to secure an accurate record of all these symptoms. Our history also included a full description of all objective symptoms which were described as the "result of physical examination." For instance, under this head, the record would show "solid, movable tumor, oval in shape, apparently two inches in length, in cul-de sac," also, in the same case, "no tube or ovary palpated in left ovarian region," and under the head of diagnosis we would insert "prolapse of inflamed, left ovary." These facts are mentioned, for it is evident that the diagnosis, which is the deduction from the premises presented, may often be inaccurate, whereas the record of symptoms complained of and of physical findings is apt to be reasonably correct, provided the observer exercises proper care in the interrogation of the patient and is experienced in his examination.

In cases presenting the usual symptoms of infection, together with leucorrhea, uterine tenderness and sometimes enlargement as well, our diagnosis of the infection referred especially to the endometrium. Where infection of a cervical laceration was evident it was assumed that extension by epithelial continuity had taken place unless it was at the same time apparent that some traumatism was present or that retention of membranes or placental remnants had occurred. Curetting was advised in these cases when menorrhagia or metrorrhagia persisted, when offensive leucorrhea occurred as a sequel of labor or abortion, or when the chronic character of the infection and the continuance of the leucorrhea gave reason to believe that granulations had resulted. Curetting was not advised in cases which showed an extension of the infection beyond the endometrium. When pus was present anywhere in the pelvis its evacuation was considered rational and it was found that subsequently our routine treatment in time controlled the infection of the endometrium When congestion and other evidence of phagocytosis were noticed beyond the endometrium it was deemed judicious to persist in local treatment until the effects of infection were removed or until the formation of pus had become a certainty Especially in extension to the mucous membrane of the tube was it considered advisable to defer a curetting because the probability of a reinfection of the endometrium was a danger which our experience taught us to be imminent Indeed, in several cases where both tubes had been removed it was observed that the infection of the endometrium still continued and gave rise to symptoms scarcely less severe than those which were noted prior to the operation

Many of the cases where operative interference was advised and where circumstances prevented the acceptance of our advice were after all forced to submit to hospital treatment owing to subsequent pus formation or the development of other serious sequelæ Nevertheless it must be stated that in a certain number of cases when, in our judgment, an operation was urgently demanded, the symptoms, under our routine treatment, would gradually improve and finally disappear

When a fluctuating tumor was felt outside of the uterus, the anamnesis and the concomitant symptoms would permit us to determine the presence of pus Its immediate evacuation was recommended in all extraperitoneal cases The etiologic differentiation was often difficult and at times impossible We felt, however, that the important point to be determined was the relationship of the pus to the peritoneum Whether the suppuration was the sequel of invasion through lymphatics or veins of vulva, vagina, cervix or uterus or had occurred by an extension through the tube to the ovary or the pelvic peritoneum was, in our judgment, of insignificant importance in comparison with the necessity of determining the feasibility of operating without danger to the peritoneum In many cases where pus was diagnosed and in certain cases where its presence was demonstrated, it was observed that the swelling would subside, the pain would diminish, menstruation would become normal in character and the patient in time would be relieved of all symptoms

Where pyosalpinx was diagnosed, an immediate operation was not usually advised Our experience showed that quite often pus, in the course of time, would be evacuated through the uterus and all symptoms of infection would disappear Many chronic indeterminate cases were observed The excursion of the uterus would be restricted by adhesions The infection would have persisted for years with irregular exacerbations Pain tenderness, leucorrhea and menstrual derangement would be associated with various effects of infection In these cases especially our routine treatment would yield most satisfactory results In all cases the subjective symptoms would in time disappear or suppuration would become localized so that proper surgical measures could be employed

The record of these everyday gynecologic cases and the details of the simple treatment instituted will be considered of but little value by gentlemen who see in every woman only a patient to be operated on I venture to hope, however, that it is not without interest for us to realize the possibility of relieving distressing symptoms, even in serious cases, when circumstances prevent hospital treatment I consider it of importance for us to understand that patients can sometimes recover without curetting, uterine dilatation or the application of caustics to the endometrium I think it well for us to know that lacerations of perineum, vagina and cervix do not always have to be closed I regard it as a matter of interest to appreciate the fact that the day of the pessary has passed and that displacements are no longer of paramount importance It is, moreover, satisfactory to note that even in cases where the consensus of opinion would pronounce unhesitatingly in favor of operation, it is occasionally possible for milder measures to succeed in the amelioration of symptoms, while the patient continues to follow her usual pursuits The inference from this observation is obvious Infection is the factor of importance in most gynecologic cases Displacement, hypertrophy and hyperplasia are essentially the result of infection or the sequel of the consecutive inflammation Infection is chiefly to be considered in the adaptation of our therapeusis Indeed in many cases no thought need be given to concomitant conditions Caustics, astringents, scarifications and many ancient practices which prevailed when we sought to control inflammation are superseded by rational methods based upon an increasing knowledge of bacteriology

CONGENITAL UTERINE ATRESIA AND DOUBLE HEMATOSALPINX

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo June 7 10 1898

BY ALEX HUGH FERGUSON, M D

CHICAGO ILL

Congenital uterine atresia with consequent double hematosalpinx is sufficiently rare and interesting to crave your attention to a report of the only case suffering from these conditions met with in my practice This was a case of atresia of the cervix uteri without the least communication between the uterine cavity and vagina The vagina was nearly normal in size There was a free communication between the uterine cavity and the enormously distended Fallopian tubes and adventitious cysts in the pelvis The accumulation of six years of the menstrual fluid was imprisoned in the uterus, tubes and acquired cysts, except the amount that had become absorbed An operation effected relief

The history of the case is as follows Mrs B, patient of Dr Dame of Winnipeg, was admitted to the St Boniface Hospital, complaining of abdominal enlargement and frequent attacks of pain in the lower half of the abdomen She was a brunette, 21 years of age, of plump and healthy appearance, weighing 136 pounds, and sanguine in temperament In the history of her development during girlhood days there was nothing unusual When 15 years old, having then to all appearances grown to be a woman, monthly pains in her breasts, back and pelvis began and several months, with three or four days of suffering in each, passed by without a menstrual flow appearing When about 20 years of age a physician was consulted, and then she was given internal medication, but no physical examination of the generative organs was made Two years were consumed in general treatment and still no flow appeared During these four years (18 to 22) her general health was good She was constipated She enjoyed life as other girls did, except at monthly periods, when pains and local pelvic distress were severer each succeeding month than during the previous one Latterly, however, attacks of cramping pains intervened between the periodical monthly disturbances, and the abdomen became enlarged, perceptible only to herself at first A few more months of suffering elapsed, the attacks becoming more frequent and the abdominal enlargement well pronounced She then consulted the late Professor Fenwick of Kingston, Canada, who diagnosed her case and opened the abdomen, in 1893, with the idea of removing the tumors He found the pelvis filled with two cysts, and so extensively attached with vascular adhesions to omentum and bowels that he thought it best to leave them alone He closed the abdomen and left the blue and vascular-looking cysts in the pelvis She made a speedy recovery from the operation Her sufferings continued, and the tumors increased in size Still her general health was fair, and she was able to do her share of home household duties A few months afterward she married and moved to Manitoba, where she fell into the hands of Dr Dame, who referred her to me for operation A physical examination revealed a prominent abdomen immediately above the pelvis, a tender mass extending on left side to a point midway between the pubes and the umbilicus, and another on the right, not so high, but equally tender The vulva, vagina and cervix appeared normal to sight and touch A uterine probe passed into os uteri about one-eighth of an inch and there became obstructed The occlusion was inspected through a straight cervical speculum There was nothing to be seen but smooth mucous membrane The atresia was undoubted The uterus was slightly movable and two tender masses could be felt, one on each side of it, and extending backward and downward, filling the pouch of Douglas Bimanually it felt more like a double pyosalpinx than anything else She had a temperature in her last attack of local peritonitis, and it was feared that the retained menstrual fluid had become infected The rectum was free from trouble Coitus was always a little painful to her at first, but she was quite amorous and enjoyed the orgasm

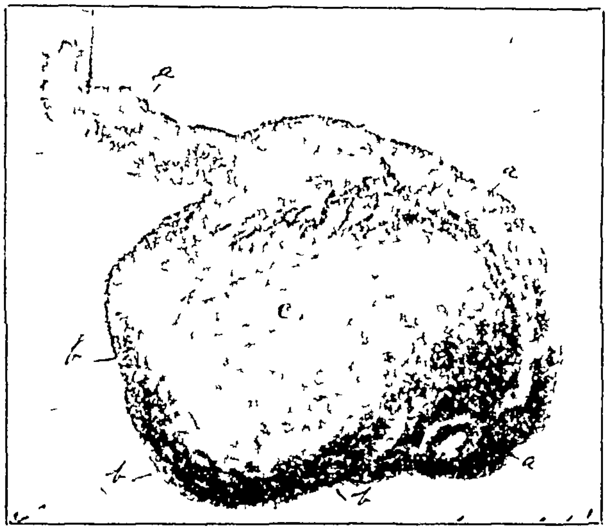

Fig 1—Left hematosalpinx four ninths actual size a fallopian tube b, ovarian tissue thinned out and forming part of cyst wall c cyst

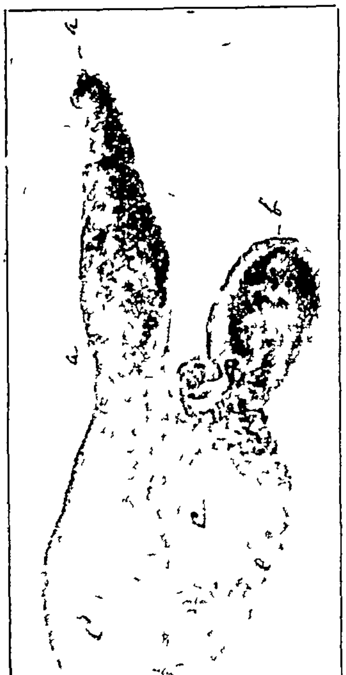

Fig 2—Right hematosalpinx, four ninths actual size a, fallopian tube b, ovary c cysts

Operation—On June 16, 1894, assisted by Drs Dame and Todd, I successfully removed the double hematosalpinx The abdominal scar tissue was extirpated, the abdomen opened, the adhesions rapidly stripped off, commencing behind the left horn of the uterus, where a free cleavage point was found No difficulty was experienced in turning out the left dilated tube and ovary without rupture of the tube or cyst I then amputated the left Fallopian tube down to the uterine mucosa The uterine cavity was filled with a dark-looking tenacious fluid and freely communicated with the Fallopian tube, which was distended with the same material An interlocking ligature of silk was applied to the pedicle and the mass cut off The hemorrhage, although copious, was not alarming and was easily controlled A probe was then passed into the uterus and extended into the cervix beyond the internal os The cavity of the uterus was not much enlarged I decided not to remove the uterus, but to open and drain it per vaginam The dark, treacly substance was squeezed out, and the hole at the cornu closed with catgut sutures The right dilated tube and ovary were dealt with in a similar manner, and the abdominal operation completed without delay On account of the extent of the raw surface left, both gauze and tube drainage were inserted The cervix was exposed through the vagina and split transversely a distance of about half an inch, when the uterine cavity was reached It was washed out and drained with gauze The patient made an uninterrupted recovery and left the hospital on the twenty-third day after the operation Three weeks afterward the silk ligature (the only silk used) on the left stump misbehaved and came away via abdominal incision, after which she remained well A year later the cervical canal was quite patulous and she was enjoying excellent health

THE SPECIMENS

Fig 1 represents the left hematosalpinx two thirds its actual size It is, more properly speaking, a tubo-ovarian retention cyst, inasmuch as the ovary forms part of the cyst wall, and the contents consist of the retained menstrual fluid Fig 2 represents the right distended tube and ovary, two thirds its actual size The ovary is distinct by itself and in a condition of cystic degeneration The Fallopian tube and adventitious cysts at its end contain menstrual fluid The plates are accurate, the drawings being made before the cysts were opened, so I shall nót describe the external appearance of the two specimens

The pathologic anatomy and nature of the retained menses are well known In this connection let me say that two fimbriæ of the left tube could be differentiated within the cyst, and the contents were free from germs

THE USE OF THE CURETTE IN ACUTE INFECTION OF UTERUS WITH ADHERENT PLACENTA

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo July 7-10 1898

BY D S FAIRCHILD, M D
CLINTON IOWA

In the midst of the discussions of the more difficult and complex questions of abdominal and pelvic surgery our leading and most eminent gynecologists, whose opinions are of inestimable value to workers in more limited fields of general gynecologic work, often fail to furnish us lessons from the results of their own varied experience in the less brilliant but equally important matters pertaining to every-day practice

I have often been impressed with the thought, if our information was definite enough in relation to the use of the curette in removing attached portions of placenta in cases of abortion, premature labor or labor at full term when infection has occured It is clear enough that in diseases of the endometrium the curette is of great value and is, as a general rule, properly used in the cases ,which come under our daily notice But in the cases where, from the retention of small masses of adherent placenta, infection has occurred, the uterine mucosa is softened, the uterine lymphatics are blocked with infectious thrombi and the temperature elevated from absorption of septic material, is it really safe to employ the curette in a vigorous and indiscriminate manner? I have frequently observed in general surgical practice that in certain cases of local infection anything more than the most careful and delicate procedures has been attended by a sudden accession of the local symptoms, together with a marked rise of temperature and have observed the same condition arise after curetting a uterus containing acute infective material

I am aware that many advocate the use of the curette in septic conditions of the uterus following abortions or after labor, when there is reason to believe that portions of placenta are still retained in the organ I have of late years been led to believe that this is not an altogether safe practice to follow Great discrimination should be employed in resorting to this procedure, otherwise much harm may be done

In cases where decomposing material affected by saprophytic micro organisms is retained in the uterus the influence of which is marked by high temperature and offensive lochia, the dull curette employed carefully for the purpose of removing from the organ the offending substance, which has but little or no attachments to the uterine walls, is an exceedingly valuable procedure, followed by irrigation with sterilized water When, however, a septic endometritis exists in connection with necrotic decidua burdened with septic germs, streptococci, the curette may become a very dangerous instrument In these cases it is quite easy to inflict a trauma which may serve as an additional means of introducing septic germs into the system The protective granulation layer which serves a conservative purpose of limiting the constitutional infection may thus be distributed, furthermore it is quite possible to penetrate the softened uterine tissue and thus lead to most disastrous results

The use of the curette in the removal of adherent portions of placenta in the early period after an abortion, before a septic inflammation of the uterus has occurred is beneficial and this together with thorough irrigation will save some of the danger of infection But after septic infection has once developed this treatment is attended, with considerable danger as I have abundant proof in my own hands and in the practice of professional friends I have no recent misfortune of my own to record for I have long since abandoned this method of treatment The removal of adherent masses under these conditions by scraping with the finger nail is not less hazardous, but even more so, on account of the trauma inflicted and on account of the risk of introducing germs which may lie concealed under the nail, especially under some nails which may be used for this purpose The conditións which we have to contend with in these cases are purely surgical and should be treated accordingly

If a surgeon, in the treatment of an infective wound, should undertake to remove necrotic tissue by violent means he would find that the condition of the wound and the general condition of the patient would become more serious In all cases of septic infection, whether of wounds or of the uterus, drainage is the first consideration together with the removal of infective material so far as possible without disturbing the boundaries which conservative efforts have placed for the purpose of protecting the system against infection It often becomes a delicate question what to do in cases of sepsis arising from the uterus The general practitioner will, in a great number of cases be called upon to decide what course to pursue, and if he has in mind the necessity of employing the curette as the most approved method of treatment he will sometimes be led into most serious difficulty and do his patient great harm A correct appreciation of the pathologic condition should underlie the measures to be employed If the examination reveals the existence of necrotic decidua, bearing saprophytic micro-organisms, giving rise to sapremic intoxication, the careful use, of the dull curette, not for the purpose of scraping the interior of the uterus, but for the purpose of facilitating the escape of the contents of the organ, followed by irrigation with sterilized water, will accomplish the desired end If, as it is sometimes found, the os is somewhat tightly closed, under the influence of an anesthetic the cervix can easily be placed in the most favorable position and sufficiently dilated for satisfactory drainage If it is found however that the uterus is swollen and the endometrium softened and infected with streptococcus only the irrigation should be employed and the irrigator handled with great care lest the violence disturb the granulation layer and expose new points for the ab sorption of infection and thus expose the system to a larger dose of poison If the examination reveals the absence of an offensive discharge, and the general symptoms are profound and not attended with local conditions other than a septic and necrotic endometrium, no local treatment should be instituted, for it is probable that the uterus is infected throughout, that a condition of thrombo phlebitis exists, that the *uterus is softened that no granulation layer exists*, and the use of the curette or irrigation can do no good, but rather harm, and should be avoided Whatever may be the merits of a vaginal hysterectomy in these cases can not be considered in this paper for the reason that the great multitude of physicians who have these patients to treat can not afford to employ it in general *It will occasionally happen that the os is closed in* cases in which it will be necessary to reach the *interior of the organ I do not remember of meeting* with a case where I could not dilate the cervix with my finger when the patient was under the influence of an anesthetic, but if the cervix is too rigid to be dilated in this manner forcible instrumental means may be employed, but great care should be observed lest a trauma be inflicted and at least afford additional facilities for the absorbtion of septic material

This paper is presented simply as a protest against what I believe to be a indiscriminate use of the curette in acute infection of the uterus While these observations may not have any application to leading members of the profession I am quite sure that the lines bounding the use of this instrument are not often enough drawn to furnish safe guides for many practitioners whose experience is more limited

I contend that great care should be observed in the use of the curette in acute infection of the uterus

In cases in which portions of placenta are adherent they should be removed by the sharp curette, but before infection has occurred, under antiseptic precautions If infection has developed, it is safer to remove all detached portions with a dull curette with[illegible]ut inflicting trauma, irrigate and drain If infec[illegible]n of the uterus has occurred without offensive [illegible]chia but with serious constitutional symptoms, no curettement or irrigation should be employed The dangers of the free use of the curette are of two kinds 1, inflicting trauma which may facilitate absorption of infection material, 2, the penetration of the softened uterine tissue If the os has closed retaining in the uterus suspicious or decomposing material, very careful dilatation should be employed under an anesthetic, detached masses removed with the dull curette and gentle irrigation employed, the whole procedure so conducted as to inflict the least trauma possible

---

THE EFFECT OF UTERINE CURETTAGE AND DRAINAGE ON DISEASE OF THE TUBES

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10, 1897

BY W W GRANT, M D

DENVER, COLO

One of the commonest diseases of womanhood, and at the same time one of the most serious in its consequences to health and life, is inflammation of the Fallopian tubes It is very generally, if not uniformly, secondary to disease elsewhere Like peritonitis, it is not idiopathic It is a common cause of sterility, either in direct consequence of the disease, or as a result of the surgical measures employed for its cure It leads not infrequently to fatal results Therefore to prevent mortality and to preserve mental stability and the functions of maternity, disease of these appendages is second in importance to no other, and appeals always to our highest consideration and best judgment

It is just to say that pyosalpinx is a purely surgical condition, requiring some form of operative procedure for its permanent cure, yet cases now and then recover without recourse to the knife As uterine endometritis is the usual cause of salpingitis, it is self-evident that whatever means will prevent, or most speedily cure, the former disease can only tend to the preservation of the functions and integrity of the tubes *Acute aseptic corporeal endometritis is* not often observed As sepsis following abortion, labor, gonorrhea or operations, is the usual cause of serious forms of uterine endometritis, and secondarily of salpingitis, it follows that prompt and efficient treatment of the endometritis is a primary necessity of the greatest importance In gonorrheal endometritis the virulence of the gonococci is not, at this stage, so great, being rarely acute even at a comparatively early period, and is not therefore manifested by the severe positive symptoms of the acute vulvo-vaginal, uretheral and cervical forms of the disease, consequently it is generally overlooked To Sanger is credited the statement that about one-eighth of all gynecologic diseases are credited to gonorrhea Unlike puerperal sepsis there are no immediate constitutional or peritoneal indications, these being dependent upon septic absorption as well as extension of the disease in one case, and chiefly extension of the inflammation to the tubes in the gonorrheal form, and usually by leakage from the abdominal ostium of the tube inducing severe violent or local peritonitis In every form of septic endometritis except the early gonorrheal, the wise and accepted rule of treatment is to clean out all debris and foci of infection from the uterus by curettage, irrigation, or both, ordinarily supplemented by gauze drainage The rule is the reverse, in fact the treatment is negative, as to the early period of gonorrheal endometritis, on the ground that to curette the uterus at this time and in this condition is to open up new channels of infection and cause a more certain extension of disease to the tubes and peritoneum I very much doubt the wisdom of the usual inaction and delay at so important a juncture The reasoning I believe more theoretic than practical The uterus is not in the soft receptive state of the puerperium, and yet we know that the mortality in the latter has been greatly diminished and should practically be abolished by early curettage, irrigation and gauze drainage *Deep and thorough curettage is specially* necessary in the gonorrheal cases, because the utricular glands are deeply affected *After curretting apply* immediately such a mixture as iodin and carbolic acid, and then antiseptic gauze for drainage and there need be little fear of aggravating the disease The surgical principle involved is the same in all—to remove the diseased tissue, which is the source of infection, and place the parts in the best possible condition for drainage and thus prevent further infection This is the dictum of modern surgery and I believe should be applied in the early period of uterine gonorrheal, as well as puerperal or other infection It is usually during the period of declension, which in the adult is not usually vaginal, that the endometrium becomes affected and there should be no great risk in curetting at such a time.

Not a great while ago I treated a case of gonorrheal puerperal sepsis in which the wife in the last four or five weeks of pregnancy contracted gonorrhea from her husband, she never knowing the nature of her disease. By all possible cleanliness and the use of sublimate irrigations to the very hour of labor I hoped to prevent puerperal sepsis. But distinct chills and temperature of 103 degrees on the third day, alternating with perspiration and attended with pain in left ovarian region, left no doubt as to the nature of the trouble. There was distinct swelling of the left tube, with a well defined circumscribed tumor at the site of the ovary, no parts of membrane or placental tissue were found in the uterus, which was immediately irrigated and drained with iodoform gauze. This was repeated several times in the course of a week, with resulting lower temperature. After a vacillating and uncertain history for two or three weeks the patient gradually improved, with a steady decrease of the tumor and temperature, which in seven weeks disappeared without operation or rupture of abscess—I supposing abscess would result. Her recovery was finally complete and she again became pregnant. The right tube was not involved. I have no doubt the sepsis was gonorrheal in origin and by extension to the tubes produced severe local peritonitis.

On Nov. 29, 1896, I was called to see Miss L., aged 20, who the night previous had slight chills with pain in the hypogastrium. About a month before she contracted gonorrhea, which had produced endometritis, suppurative salpingitis and local peritonitis, doubtless from leakage of the tube. The left tube was swollen and tender, with a distinct circumscribed swelling as large as an unhulled walnut in the left broad ligament, with a temperature of 103 degrees and a free mucopurulent discharge from the uterus. Suspecting there might be remnants of an abortion, the patient was anesthetized the second day, the uterus dilated and no evidence of abortion found. It was now thoroughly curetted under sublimate irrigation of 1 to 4000 and gently packed with 5 per cent. iodoform gauze for drainage which was removed at the end of the third day. The temperature immediately fell to 101. The operation was not repeated. For three weeks the temperature varied from 99 to 100 in the morning, to 101, and occasionally to 102, in the evening. At no time was there much tympanitis or evidence of extensive peritonitis. After this there was steady improvement, the swelling or tumor gradually disappearing and a diminishing pus discharge from the uterus, with occasional—temporary—interruptions. She was in bed eight weeks, when the tumor had completely disappeared. Slight uterine discharge continued two or three weeks longer. After curetting, the treatment was rigid confinement to bed with hot antiseptic vaginal irrigation and cotton batting and bandage to abdomen, mercury and iodid potash internally and salines, with rarely an anodyne.

This was an undoubted case of gonorrheal purulent salpingitis with severe local peritonitis due probably to leakage, and in which there was not the usual closure in such cases of either the abdominal or uterine ostium of the tube. I have examined this patient several times in the past year, the last recently and she is, under bimanual palpation as well as symptomatically, entirely well. Menstruation is perfectly regular and painless, though not quite so profuse as formerly. In such cases operation by section or even per vaginam is not advisable in the acute stage because of the greater virulence of infection and danger, unless demanded by impending general peritonitis. In each of these cases I believed that a subsequent operation by incision and drainage or extirpation would be necessary, in accordance with our more common experience. Pus tubes and small accumulations by leakage are soon encysted by inflammatory adhesions and in the absence of extending peritonitis, general infection or other grave symptoms, the indications for immediate operation are not urgent, and it may safely be deferred a few weeks.

A sister of the last patient suffered from gonorrhea about the same time, but with no acute symptoms referable to uterus or tubes, yet disturbed menstruation, irregular, more profuse and painful and ill health, caused her to consult me a year later. She was suffering from chronic endometritis and right catarrhal salpingitis, for which in January, 1898, I curetted and drained the uterus. Small strips of gauze with mild iodin and carbolic acid applications were applied once a week for five or six weeks. Her health improved steadily, and is now fully restored.

Mrs. C., aged 26, in first labor July, 1896, suffered two or three days from puerperal intoxication, or sepsis, due to retained membrane, which was promptly relieved by curettage irrigation and drainage. A few months later she experienced some pain in the right ovary and tube, which in six or eight months was greatly increased, especially at menstrual periods and when on her feet much. She was exceedingly nervous and at this time I found the uterus retroflexed and slightly adherent, the fundus thickened, as it is so commonly in retro displacements, with pain and tenderness and slight enlargement of right tube from interstitial inflammation. leucorrhea slight and inconstant. With patient in knee chest position, and by the use of two fingers in the vagina and moderate pressure, the uterus was immediately replaced, but followed immediately by increased pain, and a temperature of 101, which was reduced permanently to normal in twenty four hours by absolute quiet, which was maintained for a week, the uterine tenderness to pressure and pain in the right side continuing moderately during this time. After two or three weeks, the local symptoms being in abeyance, the uterus was curetted and drained with iodoform gauze, and a pessary (Albert Smith) inserted, and the patient kept in bed two weeks. After the operation she improved rapidly in every respect, gaining ten pounds in a month, and is now perfectly well and entirely free from nervousness and pain at any time.

In line with the foregoing treatment, the following case seems to me of interest.

Mrs. W., aged 28, confined two years before, labor normal. Returned from visit to the East latter part of October 1896, was taken early in November with mild typhoid fever. About the 20th ordinary menstruation was manifested. On the evening of the second day the flow suddenly ceased, with severe uterine colic, which continued all night. Believing the history for two or three weeks and present condition demanded a thorough and immediate investigation the patient was anesthetized, and examination revealed a rigidly anteflexed uterus, fundus slightly enlarged and a small tumor in left broad ligament. The two or three preceding menstrual periods were attended with some pain in this locality, while menstruation had always previously been painless. It was impossible to insert the blades of the dilator, so I succeeded with small conical dressing forceps in entering the uterus, when about an ounce of dark menstrual blood escaped. The internal os was rigid, the tissues hard, but yielded slowly and sufficiently to the dilator. There was no growth or debris in the uterus. It was gently curetted and irrigated and packed loosely with iodoform gauze. The pain ceased at once, and menstruation has been regular and painless to the present time. The tumor gradually disappeared without further treatment and the patient progressed and convalesced in the usual way with the fever.

This was unquestionably a case of hematometra—hematosalpinx and hematoma from gradual and finally complete obstruction at the internal os due partly to mechanical constriction from an unusual degree of anteflexion and probable cicatricial contraction at the os internum. This is an unusual complication, subsequent to labor and manifested under such conditions excited more than ordinary interest.

I have confined myself to the presentation of a few cases from my list that seem typical to accentuate certain facts and probabilities in reference to disease of the tubes, their cause and treatment I refrain from discussion at present of the plain operable cases, It is evident that some cases of pyosalpinx will recover without operation by drainage through the uterus That the best treatment of subacute and chronic and interstitial salpingitis is curettage and drainage of the uterus, using such other local and constitutional means as may be indicated or appropriate to the case, and that such treatment may be useful in some cases of purulent, not cystic, salpingitis, though not as a rule deemed wise and appropriate in acute salpingitis, yet I believe it true that rough examinations and manipulations and pulling the uterus down, thus stretching the inflamed organs and tissues, would do more harm than gentle curettage of the uterus and the application of iodoform gauze for drainage

As the endometrium is the usual channel by which disease invades the tubes, we should in all cases, infectious and non-infectious, give the former prompt and earlier consideration than is frequently accorded, and this is especially true of gonorrheal cervicitis and corporeal endometritis, which not being ushered in with severe and acute manifestations, is generally overlooked and if observed at an earlier period, as it may be, should be treated by curettage, irrigation and drainage, not only to cure the local disease, but contrary to the generally accepted opinion, to prevent the extension of the disease to the corporeal endometrium tubes and glandular tissues The left tube is more frequently affected than the right, and when the disease is unilateral, I believe the treatment advised will very generally tend to prevent extension of the disease to the sound tube and ovary, which should be preserved always when not destroyed by disease, even should it become necessary to remove the appendages of the opposite side Such possible contingencies is no defense for their sacrifice It is doubtless quite well understood that drainage is not a positive necessity after curetting an aseptic uterus under aseptic conditions, but I always use the antiseptic gauze nevertheless, and have never had occasion to regret it In two or three hundred cases of curettage, some of them septic, but most of them not, I have never seen a single unpleasant result from the use of gauze drainage Penrose in his recent excellent work says that "gauze is liable to obstruct the escape, rather than favor drainage, of discharges from the uterine cavity," and that "elevation of temperature and uterine pain are often caused by it"

I think surgeons are quite well agreed that no better drainage material exists for use in the peritoneal cavity and appendical abscesses, and I am quite certain that most of those who have used it extensively in the cavity of the uterus, are equally favorable to its use, most certainly in septic cases Yet if it should produce fever by not draining the aseptic uterus, its use would be inappropriate in the septic, and I am quite confident this is not the experience of most operators I have long been convinced that antiseptic gauze is, by all odds, the best possible material at our command for draining the septic uterus, and that it not only keeps open the cervical canal, but maintains a germicide in easy and direct contact with the whole diseased surface and drains effectively in obedience to a well-known law of physics Of course if allowed to remain longer than three or four days, it may become saturated with mucus and will not then drain so perfectly Its effect is to deplete the uterus and appendages by rapid osmosis, and a free discharge, and in a marked degree promotes involution If the uterus is well dilated, well curetted, and the gauze properly applied, by gently filling the cavity of body and neck, permitting it to protrude into the vagina, no one need have any apprehension or disappointment as to its action

DISCUSSION ON PAPERS OF DRS LEWIS, FERGUSON, FAIRCHILD AND GRANT

Dr **JOSEPH EASTMAN**, Indianapolis—Drainage which does not drain is useless, drainage which impairs drainage is worse than useless Dr Savage laid down the law with regard to uterine contraction of the fundus, that an accumulation of gauze or any substance in the body of the uterus secures the contraction of the cervix In those cases to which the Doctor referred I use a metallic substance in the cervix to secure contraction of the fundus, thereby lessening the area of surface for the absorption of septic material

In abdominal drainage for appendicitis or other purposes I can not any longer trust to gauze drainage in the lips of my wound as I have found it strangulated and drainage arrested I would suggest in the place of gauze a metallic or some hard rubber drainage, like the plug of Wylie, in addition to gauze drainage in order that it may remove material, and not place some foreign substance in the cervix which impairs drainage

Dr **ALBERT GOLDSPOHN**, Chicago—I wish to say a few words regarding the paper of Dr Fairchild endorsing his ideas *in toto*, and wish to say that not sufficient distinction is made between the puerperal uterus and the non puerperal or ordinary gynecologic uterus in pathology and treatment If we think for a moment of the consistence of the former and the consistence of the latter, how great a difference there is, and how great a difference there is in the condition of the lymphatics in the former as compared with the diminutive size of those structures in the latter, we can readily see how curettage of the puerperal uterus should not aim at doing anything to the lining of the puerperal uterus, but this measure should be resorted to simply to facilitate the extrusion of what stands on top of the mucous membrane, and the idea of using a sharp curette particularly a small one, is most abominable I have seen the evil of this repeatedly in the hands of other physicians If we use a curette at all it should be a blunt one and large so as to be able to rake as large a surface with each stroke as possible But in conjunction with the use of a large blunt curette we must bear in mind the Emmet curette forceps, which of all things that Dr Emmet's name is attached to, I appreciate the highest for this work

Dr **H G WETHERHILL**, Denver—I have maintained that the curette in acute septic conditions is very much more likely to do harm than good If used at all, it must be used to remove a foreign body and must not be used with the intention of denuding uterine surface, thus opening up new avenues for infection The position so long taken by our President (Dr Price), is the one I take, namely, that the finger is the instrument of instruments wherever it is possible to use it Where it is not long enough, then possibly a dull curette or the placental forceps of Dr Parvin or the forceps alluded to by Dr Goldspohn may be used Only a little while ago an instance of this kind occurred in this city, the case being one of induced abortion The woman was neglected for a long time until serious symptoms arose, when she was seen by one of the best practitioners in our city, who, nothwithstanding the critical condition in which she was, sent her to the hospital with a pulse of 120 and other symptoms accompanying it, and realizing that she was in a condition for radical work, he curetted the uterus The next day she was worse when I saw her with him, and we concluded that general peritonitis existed, and that there was little chance of a favorable result under any circumstances, and that one chance was in the direction of opening the abdomen and thoroughly cleaning out the focus, which had gone beyond the uterus, and in that way making an effort to save her life The abdomen was opened and the peritoneum was covered with lymph clear to the diaphragm The point I want to make in connection with this case is this What possible use is the curette going to do when the infection has gone outside of the uterus into the lymphatic and involved the peritoneum? As I have said before in this connection, you may just as well excise a vaccine mark after the eighth day to prevent the effects of vaccination It is entirely beyond your reach, and I maintain further that no man can say absolutely when that point has been passed

Dr Milo B Ward, Kansas City, Mo —I believe we have much trouble in these cases because we use irrigation We do not dilate the cervix enough and try to wash out the material we ought to get out with a curette or with the finger or tampon of gauze We dilate the cervix a little and try to wash out the débris with water, and we nearly always have a chill afterward, which means a septic infection results from water being used It is my judgment that we have more trouble caused by the finger nails of physicians and surgeons in the way of sepsis than by any other one cause When I die, Mr President, I want this epitaph put at the head or foot of my grave, "Here lies the greatest crank on finger nails in the world, except Dr Joseph Price "

Dr William H Humiston, Cleveland—In cases of delivery at term where symptoms arise indicative of retained products of conception, we should first explore the uterus without doing any damage and determine whether there is material there or not If so, remove it carefully and thoroughly cleanse the uterus You can remove it with the finger, a dull scoop, but not with a sharp instrument as with a sharp curette you will open up new channels for infection If you have a case with a history of criminal abortion where drastic measures have been used to bring it about, undoubtedly the infection has extended beyond the uterus into the lymphatics and involved the broad ligaments, etc , and you may curette such a uterus until you are gray headed and do nothing but damage

Dr F F Lawrence, Columbus—One point in regard to the second paper So far as the first paper is concerned, I am in accord with a number of the speakers that in puerperal septic conditions of the uterus we should not use a curette The point I wish to make is with reference to the shape of the uterine cavity, the angles at the fundus I believe we do harm when we express the opinion that curettage is a simple operation I believe more women have been killed by both immediate and remote conditions by the improper and unskillful use of the curette than by any other gynecologic means or effort It is utterly impossible to clear out the cornu of the uterus in diseased conditions with a large sized curette It must be a small curette If you curette the lower surface or mucosa and leave the cornu with infected material there, what good is done? What is the possibility of preventing subsequent and almost positive or continued infection extending into the tubes? As to the disappearance of pus tubes following curettage possibly such a thing is trne, but I have always feared personally to use the curette in cases in which I have reason to believe there is pus in the tube There may be a thin portion of the tube, and traction and manipulation of the uterus, which is necessary in these cases, may carry the infection to the general peritoneal cavity and develop a septic peritonitis I think we are safer in any case, where we have reason to believe there is pus, to remove it thoroughly and thus get rid of any possible source of infection

Dr T M Burns, Denver—I have a few words to say in favor of the sharp curette In the first place, I do not consider it a hoe nor a crowbar I consider curettement of the uterus an exceedingly delicate operation, and it must be done with great care It may be compared, as regards delicacy with the extraction of a cataract from the eye If we have an infected uterus with retained placenta, the retained placenta is a focus of infection, and the remnants of placenta or rotting mass should be removed promptly and as thoroughly as possible If you can do it better with your finger or dull curette, all right I can do it better with a sharp curette It does not require so much force to do it It seems to me we have to use a greater amount of force with a dull curette than with a sharp one, and thus do a greater amount of violence to the uterus If curettement is done carefully and properly with a sharp instrument there is very little danger

Dr B Sherwood Dunn, Boston—I rise to endorse the position taken by Drs Wetherhill and Goldspohn The curettement of the uterus is by far a more dangerous operation than that of abdominal section, and I think the consensus of opinion of gentlemen who have had a large hospital experience will be that more women are crippled for life by the use of the curette, either dull or sharp, in the hands of an incompetent general practitioner or a gynecologist in embryo, than any other one procedure in surgery I have myself removed not less than thirteen uteri subsequent to incompetent curettement I believe the consensus of opinion of the best surgeons is opposed to the use of the sharp curette in post puerperal conditions It is only necessary to look at the literature to ascertain the number of uteri that have been perforated by the sharp curette in the hands of careless practitioners The post puerperal uterus is a large, soft, soggy organ with practically no membrane lining it The postpartum symptoms are equally apparent, only a few hours intervening between parturition and the rise of temperature and pulse, showing postpartum infection by reason of other foci of membrane or placenta that has been left I am absolutely convinced that these foci of infection are more readily and perfectly removed with the wire curette than by the sharp instrument and it does no injury to this disorganized organ, for it certainly is disorganized at the moment you operate upon it for any post partum pathologic condition

In regard to the case reported by Dr Ferguson It was my fortune during my hospital service in Paris to have a similar case come into my hands It was so unusual that a number of my masters were present at the operation After opening the abdomen we found posterior to the uterus and filling up the posterior cul de sac a large hematoma as large as a fist, impinging upon the cul de sac of Douglas The ovary was partially coalesced upon the wall of this tumor the Fallopian tube was permeable with the cavity of the uterus, as was the one in the case recited by Dr Ferguson On the opposite side there was a pervious tube with a large edematous, badly cystic ovary unattached to the tumor, which was of minor importance, and then the one point of cardinal importance in the case was that the uterus was filled with the tumor which swelled it, and at the point of the internal os, where the congenital atresia had probably commenced, there was a sharp delimitation of the tumor The external os was conical on account of delimitation We decided that so far as motherhood was concerned the organs could be preserved We closed the abdominal incision, I resected the uterus at the point of its vaginal insertion, and there was a little white spot in the center of the uterus where the canal should have been, and with the thermo cautery I opened what should have been the canal and when I withdrew the cautery the pressure was so great that the blood and water contents were thrown over my face and garments Two years afterward this woman bore a child Three months afterward I did a subsequent operation, removing a large hematoma on the left side

Dr George J Engelmann of Boston—In regard to Dr Lewis' paper, some of the points he has made have been lost sight of in the discussion of the surgical points, which are always more interesting ' And it was well, too, that the curette was taken up, because it is a safe instrument in skilled hands, and yet I know, as you all do, of so many sad cases throughout the country But I was surprised to see in the reports of a large hospital a mortality of 2 per cent It ceases to be a trifling operation when we have this mortality in skilled hands, and from the days of the wire loop of Thomas I have fought the dull curette It is a sharp knife and a sharp curette which the surgeon wants A dull instrument will do mischief, that is, in the non puerperal uterus The dull curette is a diagnostic instrument, but only the sharp curette should be used for surgical purposes In the puerperal uterus I have used the large sharp spoon of Simon It is not a curette, but a wire loop with which we bring out the detritus Dr Lewis has called attention to the fact that we must treat cases, not as ideal circumstances demand, but as the existing conditions demand, and this is frequently forgotten, and in all our discussions I believe it is overlooked We invariably seek the treatment as it should be under the most favorable circumstances, when the facts are that we meet with cases in actual practice and must do the best we can for them under very unfavorable conditions Cases that come to our out patient departments are too much neglected in many of our large institutions We must attempt to do something for them, there may be cases which go into the hospital, and we must attempt to relieve them, and Dr Lewis has placed these points before us in his paper and has given us the methods he has pursued in ambulatory cases If a patient presents herself whose case is inoperable, she probably receives an astringent or antiseptic douche, and then goes

Dr S C Gordon Portland Maine--I fully agree with the gentleman who said that curettement of the uterus is a very serious operation A patient should be prepared for a curettement with as much care as for an abdominal section and the most important point in the curettement is that you should dilate the cervix beyond all question Simply putting in a dilator and opening it an inch or an inch and a quarter is not sufficient dilatation by any means You can not be sure of washing out the detritus in the uterine cavity until you have overcome the constriction by proper dilatation I do not like the use of chemicals in the uterine cavity but I wash out with sterilized salt solution I also believe it is important for at least twenty four hours to put in a tape, as I do not like packing the uterus, and this will give you drainage that you can not get in any other way We know how important it is to have drainage, and I believe by curettement in a great many cases, we can avoid what has been and is being done so badly, namely, operations for closure of the lacerated cervix I scarcely close a lacerated cervix now at all I find few cases in which I have to do it, but I have seen so much harm in treating so many cases of pus tubes following trachelorrhaphy, that I think it has done ten hundred times as much harm as it has done good I agree with Emmet fully in that matter, that it is a serious thing to close a lacerated cervix But the beginner in gynecology thinks that trachelorrhaphy is a simple thing to do By doing it we close the passage and we entirely prevent the most important thing, and that is drainage, and I had a good deal rather instruct young men never to do a trachelorrhaphy, but to resort to dilating and curetting, telling them that they will do the patients a great deal more good and very much less harm

Dr **Emory Lanphear**, St Louis—If you will but recall the pathology which underlies postpartum and post-abortal septic infections you will come upon a common plane In the case of saprophytic infections we have no implication of the uterine mucosa until very late, in which instance the dull curette or the finger, after proper dilatation, is all that is necessary When we have the staphylococcus pyogenes aureus, albus and citreus affecting the uterus, then must we remove the infected tissue, which is the uterine mucosa, and which can only be accomplished by the use of the sharp curette When we have streptococcus infection, no curette under heaven will do the patient one bit of good

Dr **Lewis** (closing the discussion on his part)—Four years ago, at the time the large dispensary of the Chicago Policlinic was placed in my hands, I had been in the habit for many years of having charge of the gynecologic and obstetric wards of the County Hospital of our city I had operated on pyosalpinx and the usual diseases, and I had absolutely no knowledge of the cases presenting themselves at the dispensary The first day I assumed charge there, the first patient who presented herself had a pyosalpinx as far as I could diagnose it, and I advised immediate operation She said she was unable to go into the hospital because her children were ill and she had to take care of them The next patient had a laceration of the perineum with rectocele, I advised operation in her case, and for sociologic or economic purposes, she was unable to accept that advice And so it went on, case after case appeared at the dispensary which in my judgment required surgical interference, and they were unable to accept the advice I gave them Under the circumstances I felt it was necessary to do something, and I persisted in the treatment which I have outlined to you today, and the results were gratifying, and in many instances most surprising, to me For that reason I have taken the opportunity of presenting to you cases that will prove very surprising to others as well as myself

I should like to go into the subject of the use of the curette, but time does not permit, and I will say nothing further about it, except to remark regarding the statement made by one gentleman who spoke of perforations of the uterus, and intimated that the sharp curette was responsible for such perforations more frequently than the dull curette As a matter of statistics, the uterus has been perforated with dull instruments more frequently than with sharp curettes The probe, the uterine sound, and the silver catheter have caused more uterine perforations than sharp instruments This is simply a matter of statistics, which I have looked up

Dr **Grant** (closing the discussion on his part)—There was one statement made by one of the speakers which I think should not go unchallenged, namely, that because the infection has gone beyond the uterine endometrium and has infected the tubes, it is useless to remove the diseased condition in the uterus I do not think any more fallacious surgical principle could be advanced, that simply because we can not reach the disease all at once we should do nothing That is about the feeling of the criticism of one of the speakers, who believes that we should not curette a uterus which is really the *fons et origo* of the trouble The most important thing is to scrape away all of the diseased tissue that has caused the trouble and which if left continues to infect neighboring structures

I very much regret that some of those gentlemen in the discussion did not devote a little more time to those cases of gonorrheal origin which are so very frequent and of very great importance I was in hopes of hearing something from some of my distinguished friends here in reference to the early treatment of these cases They are certainly common and overlooked These cases should be curetted more frequently

With reference to the question of curettage and drainage, one of the gentlemen made the statement that this practice might cause infection on account of the free raw surface which is made by the curette I have stated that if the septic material is thoroughly removed there was very little danger As a matter of fact, there are few men who have had a large experience in the early treatment of gonorrheal cases of this form That is why I introduced the cases I did in which I have had a surprising experience

PROPHYLAXIS OF DISEASES OF WOMEN

Presented to the Section on Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY DAVID W BASHAM, M D
NEAL, KANSAS

Since the science of hygiene is justly allowed to occupy so important a place in the literature of general medicine, I deem it a duty incumbent upon those engaged in gynecologic and obstetric practice to endeavor to elevate the prophylaxis of the diseases of women to the same exalted plane

Generally the average gynecologic essayist, disdaining to concern himself with the ordinary affairs upon which our clients so much need good and wise counsel, endeavors to elucidate his own or some fellow practitioner's method of extirpating the internal genitalia, or some part thereof, from the female pelvis All of this is laudable, because it serves a beneficent purpose as concerns both mankind and the profession of medicine But if it be noble and great to emancipate the human body from disease and suffering by the dexterous use of the scalpel, scissors, and sterilized catgut sutures, how much better is the rendering of these appurtenances of our art unnecessary This paper is not an argument for conservatism in the treatment of existing pathologic conditions, but a simple effort to disseminate the doctrines of preventive therapeusis As often as I am called upon to disembarrass a patient of important organs rendered useless and intolerable through pathologic metamorphoses, the result, perhaps, of a non-aseptic accouchment, I promise myself to labor with renewed assiduity to inculcate the tenets of preventive medicine, which shall be the medicine of the future

Owing to the anatomic construction of woman, the female pelvic organs are far more vulnerable to the influence of pathogenic agents than are the analogous organs in the opposite sex, because in the former a readier and more commodious medium of communication exists between the cavities of the genital tract and the atmospheric world The same anatomic design conduces to the easy genesis of pathogenic micro-organisms within the series of cavities constituting the genital system This arrangement, which is indispensable to the perfect operation of the viviparous plan of reproduction, which provides that after having attained a certain stage of development within the maternal body, the fetus shall be forcibly extruded into the world, unavoidably entails a greater or less degree of traumatism to all the structures concerned These facts serve to explain why the pelvic organs in woman are so much more frequently the seat of pathologic changes than the same organs in man All of the elements necessary to the process of infection are present in the act of childbirth, and also in a less accentuated form in many other acts inseparable from the functions peculiar to woman The things requisite in the process of infection are violence, to produce a breach in the tissues sufficient to admit of the ingress into the circulation of germs or putrid material, and the existence of certain conditions which facilitate the introduction of such germs or putrid material into the cavities of the system of hollow organs known as the genital tract, and where the breaches into the circulation exist, and where also are found fluids and coaguli to serve as media and nidus wherein rapid multiplication takes place The question of prophylaxis of diseases of the female pelvic organs then resolves itself into two principal propositions the first of which consists in the minimizing of traumatism to the genital mucosæ, and the second is the preclusion of the introduction of disease micro organisms from the extraneous world into the hollow organs constituting the genital system

It will be seen then that the major part of gynecologic prophylaxis rests in the degree of perfection with which the art of obstetrics is carried into practice It is a fact beyond refutation that an enormous proportion of all gynecologic affections have their origin in the parturient act, and the week in bed that follows Endometritis, salpingitis, ovaritis, cystitis, and nephroptosis, are some of the conditions which are *often simply sequelæ* to the act of parturition and the puerperal month

So much depends upon the work of him who essays to minister to the needs of woman in the hour of travail, that it is not easy to overestimate the importance of the offices of the accoucheur in the matter of diminishing the frequency of pelvic diseases in the female The scientific obstetrician has well accomplished his duties, so that it is no longer a question of profounder knowledge, but simply a matter of the better application of the principles already well known to the profession Of all the members of the medical fraternity who should act with an eye to the future condition of his client, there are none upon whom this obligation should rest with greater weight than the obstetrician The prompt application of surgical principles to the treatment of traumæ received during childbirth may avert many of the troublesome sequelæ to that act which often terminate in serious pathologic changes, and often demand radical measures for relief It is not at all improbable that uterine cancer is frequently the result of a neglected cervical laceration The immediate restitution of a lacerated perineum may avert the occurrence of a case of prolapsus which would require hysteropexy, or even a case of procidentia uteri with chronic endometritis and hypertrophy of the organ, which might demand hysterectomy to effect a cure Thus it is throughout the entire catalogue of minor accidents and the corresponding surgical procedures for their relief

There are some grave conditions which owe their inception to accidents occurring during the age of pubescence, or during the first years of menstrual life It is here that the general practitioner might find an opportunity to enhance his usefulness at the expense of the neurologist It is reasonable to believe that many cases of aberration of nerve function might be prevented by well-directed medical attention during the early years of menstrual life

In sum the prophylaxis of the diseases peculiar to woman may be embodied in a more perfect application of the principles of obstetrics in actual practice a profounder understanding of the accidents occurring so frequently at the age of pubescence, and finally greater attention to the hygienic regulations which should govern daily life

GONORRHEA AS A FACTOR IN PUERPERAL FEVER

Presented in the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY ALBERT H BURR, PH B, M D

ADJUNCT PROFESSOR OF PRACTICE OF MEDICINE COLLEGE OF PHYSICIANS AND SURGEONS ATTENDANT PHYSICIAN TO PROVIDENT HOSPITAL
CHICAGO

The methods which have revolutionized modern surgery as the direct results of the teachings of Lister have been more or less efficiently carried out in the practice of modern obstetrics The new science of bacteriology and the accumulating evidences of the pathogenic nature and far-reaching effects of certain micro organisms have invested the subject of the prophylactic, aseptic and antiseptic protection of the parturient with increasing interest and importance Notwithstanding the advancements along these lines, the query arises why is there not greater freedom from septic complications and fatal issues in the service of those who carry out the most approved measures in the practice of midwifery? In other words, are there not frequently sources of danger within the mother herself, antedating childbed, which ordinary methods fail to avert? I desire to emphasize the importance of these vital questions

Since the discovery of the gonococcus which Neisser announced as the specific cause of gonorrhea, in 1879, two important discoveries have placed his claims beyond all cavil, first, the Gram method of staining, by which this germ is differentiated from all other diplococci, and, second, the improved culture methods of Bumm and Wertheim (1889-1891), by which its true specific character was established by the four immutable laws of Koch It is now possible to scientifically demonstrate the multiple roll of this ubiquitous germ in its capacity for pathogenic mischief A glance at the biology of the gonococcus will help us better to comprehend its possibilities for doing harm in the puerperium Its habitat is the mucosa and glands of the genito-urinary organs of the human race It is not known to exist anywhere in nature apart from the human body It perishes quickly when removed from its host It is cultivated with difficulty on nutrient media of human blood serum or urine It dies very soon in water, loses its virulency when thoroughly dried, and is easily destroyed by ordinary antiseptics Notwithstanding all this the germ is most persistent in its normal surroundings It is able to exist in various degrees of chronicity for indefinite periods of months or years, retaining its power to invade new territory and regain its old-time activity under favoring circumstances It requires no solution of continuity or lesion of any nature to prepare the soil for infection It is able to penetrate readily the epithelial, follicular and glandular structures of the mucous surfaces everywhere Nor does it stop here It also penetrates the submucosa and adjoining muscular walls It makes its destructive pilgrimage through lymph channels into the circulation itself and sets up dangerous lesions in distant organs like the heart, brain and articulations This power of extending its field of operation by penetrating almost every tissue of the body together with its persistence in favorite localities while awaiting its opportunities constitute its most dangerous properties as a pathogenic organism in childbirth

Again it is essentially an irritant pu [illegible] germ advent upon uninfected mucosa is quickly followed by copious, purulent discharges in which at first no other pathogenic germs are found. It is not self-limited and hence immunity is never established, although degrees of tolerance in the form of chronic pathologic changes in members may exist for indefinite periods. According to Finger and others, the nature of the epithelium of the mucosa has an important bearing on the behavior of the gonococcus. The germ remains superficial on mucosa covered with squamous epithelium, but it quickly penetrates into connective tissue under cylindrical epithelium. He found that injections of pure cultures into the peritoneum and joints of animals produced rapid and acute inflammations, while injections of filtered culture fluids gave negative results, showing that the pathogenic effects were caused by the living germ itself and not by its products. Hence we may readily understand its ability to produce abscesses wherever swollen ducts, canals or tubes hinder free drainage or where trauma has given it entrance to the systemic circulation. Bujwid has reported the case of a gonorrhoic male who was seized with a chill two days after catheterization. These chills were repeated several times in the next ten days, followed by intramuscular abscesses in various parts of the body, the pus from which afforded pure cultures of the gonococcus, thus, showing its ability to produce pyemic conditions. Not only is it a source of danger in itself, but its presence prepares a suitable field for the culture of other germs, even more dangerous in the presence of the slight or severe trauma of parturition. The lowered vitality of infiltrated mucous and submucous structures, the hypersecretion of muco pus, the débris of swollen and exfoliated epithelium offer a most favorable soil for mixed infection. The gonococcus will share its possessions in apparent harmony with other pathogenic germs, or at an indefinite period, quit the claim in their favor. We believe these facts are overlooked in estimating the rôle played by the gonococcus in childbed fever. We have developed slides from a case of chronic gleet in a patient suffering from arthritis of the knee, two years after his acute infection, in which the pus cells contained gonococci, while the field surrounding these cells was filled with staphylococci. We have found the same microscopic showing in discharges taken directly from the cervix uteri of a patient suffering from her first attack of salpingitis, four years after her primary infection by her husband and three years after her only confinement, at which time she suffered from febrile arthritis of the shoulder, her babe having gonorrheal ophthalmia at the same time. Pyosalpynx and a laparotomy are probabilities in her future history. It is to be hoped she is now permanently sterile. In the gonorrhoic female sterility is a conservative process, a blessing in disguise.

Having reviewed some of the most important characteristics in the life history of the gonococcus, let us examine the opportunities it has for complicating and endangering the puerperal state. It has been variously estimated that from 10 to 30 per cent. of all women became gonorrhoic. I believe the latter figure is nearer the truth. This is better understood when we consider that the majority of males become infected sooner or later, and that the greater portion of them remain in uncured chronic and latent stages for indefinite periods, during which time they are capable of imparting the disease. Indeed, the proportion of both sexes who never are completely cured is much larger than is commonly supposed. It is doubtful if chronic or residual gonorrhea in the female, by reason of its inaccessible location, is ever completely cured during her child-bearing years. If the disease were confined to the vaginal mucosa, lined as it is with squamous epithelium, it would remain superficial, as Finger has pointed out, and would be accessible to antiseptic treatment. In its urethral and vulvar locations it could be readily dislodged also, but we must remember its predilection for the ciliated, columnar epithelium of the endocervix, endometrium and fallopian tubes, and its rapid penetration of this kind of epithelium to deeper structures. Fournier's statistics show that one-fifth of all women contracting gonorrhea develop salpingitis. If this be double, sterility is usually entailed (Terillon). The radical cure of such a state is an almost hopeless problem.

Wertheim, discussing endometritis before the German Gynecological Society said, "Next to the urethra, the uterus is the favorite seat of gonorrhoic infection. It is directly infected and may be confined to that organ. It exists as an interstitial endometritis. Krönig found gonococci in many examinations of the lochia along with other pathogenic micrococci, especially strepto- and staphylococci." He concludes that gonorrhea extends to the endometrium during the puerperium, and may give rise to fever without a trace of mixed infection.

At the puerperium the disease may be recent, in the form of acute or subacute urethritis or vulvovaginitis, or it may have existed in chronic forms a long time in such favorite localities as the glands of Bartholini, in the columnar epithelium and glands of the cervix, or having preceded conception, there may be a chronic gonorrheal salpingitis or unilateral pyosalpynx. Fehling observes that gonorrhoic endometritis and perimetritis in pregnancy is now an established fact, and urges careful treatment of women who have been infected during or after conception, to prevent symptoms of a still graver character. Max Madluer demonstrated the ability of the gonococcus to pass from the endometrium into the uterine muscles and set up inflammatory processes. This, he says, is especially the case in the puerperium, and may result in abscess formation. Infection of the peritoneum through the uterine wall is a possibility, and, he believes, explains the fact of perimetritis without implication of the adnexa.

Fehling says absorptive fever is not rare in patients suffering from gonorrhea during pregnancy, and pus-tubes are often noted. In such a state of affairs parturition opens up many channels for infection and constitutional symptoms of varying degrees of sepsis. A ruptured perineum, a vaginal erosion, a lacerated cervix, a denuded placental site, are so many open gates for the invading gonococcus or for other dangerous germs, which might not have been present but for a soil rendered favorable by gonorrhea. If pyosalpinx exists, the condition is fraught with the gravest possible dangers, which human skill may be powerless to avert. It is evident, then, that many mothers run the gauntlet of hidden, and oftimes unsuspected, foes during confinement on account of gonorrhea alone.

DIAGNOSTIC POINTS

If possible, an early examination should be made of every prospective mother, especially if she be a primipara, for the reason that this class is in the greatest danger, because of more recent infection and less constitutional tolerance of the germ 1 Any muco-purulent discharge from urethral, vaginal or cervical orifices should be regarded with suspicion and should be submitted to microscopic proof and treated according to findings 2 The existence of a vulvar abscess or the discharge of pus from a Bartholinian gland on pressure is presumptive evidence of gonorrhea 3 The presence of gonorrhoic ophthalmia in the new-born is positive proof of maternal infection If the mother be a primipara, she will be extremely fortunate if she escapes puerperal complications 4 The presence of arthritis with pyrexia during gestation or during the puerperium makes the diagnosis of gonorrheal infection highly probable Gonococci have been found frequently in inflamed joints as the active cause of irritation, swelling, pain and fever, which are the expressions of a systemic infection, erroneously styled gonorrheal rheumatism I have seen acute-febrile arthritis in the seventh month of pregnancy, which was not correctly interpreted until it occurred in childbed, without any pelvic symptoms whatever Gonorrheal ophthalmia in the babe, however, cleared up the nature of the ante- and post partum arthritis of the mother

In a series of cases reported to this section by the reader at the Atlanta meeting of 1896, there were three fatalities after perfectly normal labor in primipara, in which gonorrhea was a clinical feature during pregnancy In one of these sepsis developed twenty-four hours after delivery, from the discharge of an extremely fetid tubal abscess into the uterus when the detached-secondines had freed the uterine orifice, resulting in general peritonitis and death on the seventh day The second died from recurring pelvic peritonitis and exhaustion one month after confinement The third, with no pelvic symptoms whatever, developed multiple arthritis with hyperpyrexia and acute systemic infection, which terminated her life on the twenty-seventh day, possibly from ulcerative endocarditis Of the non-fatal cases, the mothers all had either acute metritis or arthritis, or both, with chills and pyrexia, and all of the babes had ophthalmia microscopically shown to be gonorrhoic

TREATMENT

1 *General prophylaxis*—Prophylactic measures are of the greatest importance These may be 1 Educational Our youths should be instructed at the proper age in our public schools concerning sexual physiology, sexual hygiene and sexual morals 2 Executive, through the sanitary supervision of all classes and individuals liable to spread gonorrhoic infection 3 By legislative enactments, regulating the marriage license We believe that no candidate for marriage should receive a license who has not filed a certificate of health from a competent medical official showing freedom from all contagious diseases

2 *Specific prophylaxis*—Once a female is known to be infected with gonorrhea, her treatment should be conducted even more persistently and more carefully than in the male, for the infection more readily passes to inaccessible locations and the remote effects are far more subversive of health and dangerous to life itself It is unfortunate for women that gonorrhea is so often overlooked in their sex in its acute and subacute stages Undoubtedly if it were recognized and some sort of antiseptic treatment instituted as early and universally as in the male sex many disasters would be averted The plan of treatment depends upon location and the stage of the disease So long as it has passed no farther than the urethra vulva and vagina and their special glands drainage and irrigation with solutions of silver or potassium permanganate are effective If the endometrium is involved without tubal infection, curettage and irrigation may cure If the tubes are infected, as evidenced by acute or chronic salpingitis or pyosalpinx and recurring pelvic peritonitis no local treatment can eradicate the disease If, now, infection has taken place at the time of or during the term of gestation, much may be done to avert childbed complications Every pregnant woman should be carefully inspected at least a month preceding child-bed Her physician should know of the sanitary condition of her parturient canal and relevant organs in order that her puerperium may be free from all preventable dangers Inspection of parts and microscopic examination of suspicious secretions from urethra, vulvar glands, vagina or cervix uteri will determine the question of infection Urethral or vaginal irrigation of potassium permanganate solution, 1-2000, drainage, curettage or dissection of infected vulvar glands and topical applications of nitrate of silver solution, 10 per cent to the endo cervix will place a patient in the most favorable condition for her confinement

3 *Child bed treatment*—Ante- and post-partum diagnostic symptoms of gonorrhoic infection have already been given Now, that such a contingency exists, what should be the treatment in child-bed? Vaginal irrigations of sterilized water or antiseptic solutions after normal labor have been generally abandoned by obstetricians, for obvious reasons Labor complicated by pre existing gonorrhoic infection is not a normal state, and I believe justifies the irrigation of the vaginal canal twice daily with warm potassium permanganate solution, 1-2000 The procedure is devoid of danger and may prevent extension to the endometrium appendages and the pelvic peritoneum In the event of symptoms showing endometritis, intra uterine irrigation carefully done with the same solution has given good results and I believe is rational treatment Other external local applications and internal systemic treatment for depletion, sedation and elimination will suggest themselves according to the exigencies of the case In the fulminating forms of puerperal fever, little can be done If these are due in any way to gonorrhea, it is from secondary mixed infections of virulent types made possible through previous gonorrhea Here the antitoxins are on trial with some promise of success

CONCLUSIONS

1 Gonorrhea is a widely disseminated disease, especially persistent and dangerous in females

2 Gonorrhea is directly or indirectly a factor in puerperal sepsis and accountable for a larger percentage of complications and fatalities than commonly supposed

3 Prophylactic measures, general and specific, are most important in averting the septic dangers of childbed

Antiseptics and Diphtheria Toxins—Salkowski states that guinea pigs survive fatal doses of diphtheria toxin if salicyl aldehyd, carbolic acid or formalin be combined with it The toxin seems to be chemically rather than mechanically affected and the body temperature is evidently a factor in the result —*Munich Med Woch*, June 23 other parts of the intestine, but the longitudinal bands and *colica epiploica* will enable us to identify it readily in almost every instance, and a knowledge of its mesenteric or closer attachment to the parietes will be of material aid In most cases, we should be able to pick it up and be sure of what part we have at once, without even the aid of vision In appendectomy we often find the organ so firmly bound down by adhesions that it is with the utmost difficulty that we can separate them, in fact, often it is quite impossible In these cases, if we can identify the peritoneal layer at any point and gain a start underneath it, we can usually enucleate the organ very rapidly and easily, doing all our separation work between the peritoneum and muscular coat When so done, we can close the peritoneal rent and leave no denuded surface to form other troubles We are again making use of our old plan in dealing with the Fallopian tubes Many times our work will be greatly facilitated if we will first ligate the base of the appendix in two places, cut between ligatures, and start our enucleation process at the base, between the diverging layers of the mesentery I have found this plan of especial help when the appendix tip was buried deeply in the pelvis under dense adhesions passing down over the external iliac artery and in contact with the ureter In surgery of the gall-bladder and ducts, too many surgeons habitually depend on finding the fundus of the gall-bladder as an anatomic starting-point, forgetting that it may be congenitally absent, or the trouble for which the operation is undertaken has produced inflammatory adhesions and possibly buried the fundus and body of an atrophied gall-bladder so completely that he who persists in his search for it as a guide to subsequent manifestations may tear off its attachments to the liver and cause troublesome hemorrhage, and be no nearer than before to a recognition of the cause of the trouble, which is, in all probability, located in the cystic, hepatic, or common duct In such cases, we will gain much time and save ourselves much annoyance by first locating the hepatico-duodenal fold of peritoneum, or grasp in it the common bile duct, hepatic artery and vena porta, with the foramen of Winslow beneath and hepatic and cystic ducts to the right, we can at once determine, in most cases, the location of the difficulty for which the operation was undertaken, if it pertains to the gall circulation, and with much less danger than by way of the fundus

In perineorrhaphy work, too many cases have only a skin support, the normal perineal structures proper being in no sense restored as a supporting organ by the operation intended to relieve various forms of prolapsus, the defect being only hid, the result is altogether disappointing to the patient and surgeon, and brings this much-needed operation into disrepute

In the flap splitting method, in some cases the recto vaginal septum is not located, but the vaginal mucosa only is raised, and when the sutures are introduced they cause strangulation necrosis of the vaginal flap or a large part of it, because it is impossible to get sufficient hold upon so thin a tissue without seriously involving its blood supply in the suture clasp The same danger occurs from a little carelessness in forming the flap on the opposite side, and there is great danger of fecal fistula If, however, the recto-vaginal septum is followed, the separation may be made extensive enough to give any desired result in a new perineum, and no harm will result, if any care be used in suturing I am convinced, however, that the general plan of introducing sutures in the old through-and-through manner to the highest point of separation is a great mistake, and many such sutures will cut deeply and cause prolonged irritation and often a tender perineum

Much better results will be obtained by introducing several layers of buried absorbable sutures, which will make a more perfect approximation of all parts of the deep wound If a through-and through suture is used, I am sure that better results are obtained by using here the same principle that Fowler applies in his 'figure 8" abdominal method, because it secures more perfect approximation of all parts than by the old plan The purse string tendency of the old suture method makes our resulting perineum only one-third to one-half the depth and corresponding strength we originally supposed we would be able to attain

---

TOTAL REMOVAL OF STOMACH FOR CARCINOMA OF PYLORUS—RECOVERY

BY G CHILDS MACDONALD, M D (BRUX, HON)
F R C S Edinburgh, Exam M R C S, England Fellow Medico Chirg Society, London Late Resident Surgeon Royal Edinboro Infirmary Lecturer on Surgery, College of Physicians and Surgeons, San Francisco, and Visiting Surgeon, St Mary's Hospital
SAN FRANCISCO CAL

J Patritti, Italian, aged 38 years, occupation, dairyman, admitted to St Mary's Hospital on June 15, 1898, suffering from a tumor of the pyloric end of the stomach The usual symptoms associated with that condition were present, as the patient was unable to speak English but imperfectly, no definite history was obtainable, but so far as we could gather, he had been ill, probably unable to work, for two and one half months prior to entering the institution He stated he never had any previous illness, moreover his immediate relatives were free from cancers or tumors He complained of pain in the epigastric region, paroxysmal in character, vomiting and weakness The physical examination revealed marked general emaciation, a distinct movable tumor in the right hypochondrium, the stomach was dilated and on stimulation of the epigastrium by rubbing could be made to contract violently, attempting to pass its contents on to the duodenum By the clinical picture presented, I concluded the growth must have extended, at least, over a period of six months His weight, unfortunately, was not taken Feeling the hopeless condition of the patient, I decided to remove the whole of the stomach To this he consented He was accordingly brought into the operating room at 9 A M, June 15, 1898 Ether was the anesthetic used, which he took badly, and half the operation was done without any, stimulants having to be administered hypodermically on several occasions

The incision was commenced at the tip of the ensiform cartilage, continued down over the linea alba to half an inch below umbilicus on the right On opening the abdomen the stomach and liver came into view, omentum devoid of fat, there were no adhesions The first part of the duodenum and pylorus were freely movable The great omentum was tied in portions about half an inch from the stomach and cut away to a point midway between the first part of the duodenum and splenic end of the stomach The gastric hepatic was treated in a similar manner, to half way along the lesser curvature, fine catgut was the material used The duodenum was now clamped in two places and the gut divided between the forceps on the distal end were covered with rubber, the cut ends were immediately packed around with gauze to prevent infecting the peritoneum, by this means the pyloric end of the stomach could be drawn out of the abdominal cavity The remaining portions of the gastrohepatic omentum and of the gastro omentum were treated in a similar manner The esophagus, which was elongated and drawn down, was clamped and divided as had been the duodenum, the stomach was then removed It was found the duodenum and esophagus could be brought together with a moderate amount of tension A large sized Murphy button was used to complete the anastamosis, but it was found necessary to use several reinforcing sutures for the anterior two-fifths of the duodeno-esophageal juncture, the material used for this, as likewise the running thread, was silk The abdomen was closed in the usual way From the time the man commenced to take the anesthetic till his removal from the table a period of ninety minutes had elapsed, toward the end he showed a considerable amount of collapse, this continued for four hours, despite hot water bottles, flannels and stimulation by hypodermics of whisky and strychnin Toward the afternoon he rallied, by 7 P M, his condition became again alarming, the pulse ran up to 120, weak, compressible and irregular, in fact, he presented all the symptoms of so-called cardiac failure Enemas of hot coffee, together with hypodermics of whisky and strychnin, were administered without any appreciable effect, hot water was also tried by mouth Sitting by the patient's bed, feeling the failing pulse it struck me the condition presented more the phenomena resulting from inhibition of the pneumogastric and the uncontrolled action of the sympathetic, I therefore administered a hypodermic of 1–100 digitalin The effect was immediate, the pulse dropping to 110 and steadying From now on he continued to improve the digitalin being continued at intervals as required Urine and feces passed voluntarily at 10 30 P M Nutritive enemata were given through the night The following day he was given half an ounce of peptonized milk and whisky by mouth every hour Larger amounts by rectum at similar intervals Respiration 30, temperature 101, pulse 102 June 17, pulse 118, respiration 23, temperature 101 2 Nourishment as before June 18, pulse 106, respiration 18, temperature 100 8 Amount of nourishment doubled, per mouth, but given every two hours, white of egg and beef peptonoids added enemata as before June 19, pulse 82, respiration 18, temperature 99, rectal feeding stopped Chicken broth added, bowels moved June 20, pulse 80, respiration 18, temperature 98 4, egg-nogg added June 21, pulse 82, respiration 18, temperature 98 3, given chicken broth thickened with rice flour, corn-starch and wine jelly bowels moved June 23, wound dressed first time today, had healed by primary union about half of the sutures removed, patient hungry, wants beefsteak July 3, button passed Given California oysters and minced chicken Bowels act once daily, evacuations solid July 10, sat up From this on patient improved rapidly, gaining strength and flesh On July 15, he informed a fellow countryman in the ward, he intended going down town to see a friend and do a little shopping, he slipped out of the ward and was discovered by me at 1 P M, carrying a grip-sack which contained his purchases He was indignant at my putting him on a car and taking him back to St Mary's, saying he "felt good" and was "all right" The grip sack weighed 12 pounds and the man turned the scale at 105 pounds He then made us understand that his usual weight was 135 pounds July 21, patient has not started off on any more excursions, but contents himself with playing poker and walking round the hospital grounds His weight today is 107 pounds

Exterior of stomach, stomach much contracted due to formalin solution being too strong 1 Esophageal end, 2 Duodenum

Interior of stomach showing growth 1 Pylorus

Photograph of patient taken twenty five days after operation

I have to thank Drs Frazer, Kingwell, McMonagal and Bailey for their kind assistance during the operation, also Dr Keenan, our resident on the third floor, for the great interest and trouble he took in the after-treatment, Sister Mary Carmel for the individual and close attention she gave to the nursing There is no doubt that I have to thank Dr Keenan and Sister Mary Carmel for the successful termination of this very interesting and instructive case

July 28, patient left the hospital and returned home and is feeling well and in every way satisfactory

SELECTION

Repulsed by Fever—It is fortunate that the headlong valor of the American forced the surrender of Santiago But for the sheer fighting which was won against all odds, the Santiago campaign would now be ending in ignoble failure The army which Spanish arms could not defeat is repulsed by fever and must come North The result was foreseen by every one aware of the only conditions under which white men can wage war in the tropics But countries, like men, never really learn by the experience of others The English Army has learned how to conduct a campaign in regions like Cuba and in time the United States will Until we are willing to learn, we shall have the experience of Santiago White men, the English have learned, can not campaign in the wet season in the tropics in the open unless they have an army of attendants The English expedition which went to Abyssinia just thirty years ago under Lord Napier of Magdala, had 16,000 English soldiers and 32,000 native attendants to take care of them All English tropical expeditions are organized after this fashion Every regiment has its watermen and its tent men, its carriers and its cooks A white man in the tropics has a store of cold climate force, vigor, energy and bravery which makes it easy for him to sweep through any tropical fighting line he meets But he cannot fight the climate He can not endure rain by day or the damp ground by night Fresh from the North, for three or four weeks he will endure these things with a glorious disregard of experience It is as Franklin said, "a dear school, but fools will learn in no other," After three weeks of exposure fever taps the incredulous Northerner on the head and he wakes some morning to find he is too ill to move As General Ames says "A full list of the sick would be a copy of the roster of every regiment The only mercy is that there are only 16,000 men at Santiago who have won a great victory and brought peace instead of 60,000 men about the lines of Havana, lines too strong for assault and needing "regular operations" and weeks of fever stricken delay The lesson is clear For the work of occupying and garrisoning Cuba, the United States must organize an army on the British Anglo Indian plan The core of the army must be "immune" whites from the South and negro regiments No men unacclimated by some experience are ever sent in the British Army to the tropics and men under 25 are excluded altogether from such service But even regiments thus constituted can not live in the physical conditions usual in campaigning in the temperate zone The fighting man in the tropics must be taken care of A force of laborers, all tropical, must be hired Instead of feeding the idle at Santiago on landing, not an able bodied man among the natives should have been given a ration unless he was willing to work, and strict military discipline should have ended the fatal and inexcusable nonsense of precious Northern fighting material courting fever and inviting death by digging and pack carrying when idle Cubans were standing around eating United States rations If this course had been followed, while fever would have come it would not have demoralized and broken the strength and fighting force of brave men as it has at Santiago and assuredly will at Manila The prediction is easy to make, it is based on two centuries of Anglo Indian experience—the instant General Merritt's force moves from its lines and begins active operations in the field, where the men have to get wet, unless they are provided with a plentiful supply of coolies to fetch and carry and spare the white men, tropical fever will mow a broad swath through the strong ranks and a quarter will never come back These are words of truth and soberness Every medical man and every man of tropical experience or knowledge knew that the Santiago campaign was a terrible risk The nation deliberately matched with fever and death for victory and won in the grim game by overmastering bravery But for white men nothing foils tropical fever except close personal care If a white man in the tropics has to dig and get wet and do common labor he collapses in all cases and dies in about one half the instances The United States has to occupy and, for some time, to garrison Cuba—Porto Rico is higher and healthier Unless there is to be a terrible waste of life, the Anglo Indian plan of minutely caring for white men in the tropics must be adopted in Cuba Any other plan is sure to end like the present collapse at Santiago due to climate, doubtless aggravated by faulty staff administration, but primarily due to climate—*Press*, Philadelphia, August 5

The history of the Panama Canal where the French Engineers had plenty of well equipped hospitals, and an abundance of skilled attendants, shows that the fearful sickness roll must be due to inherent conditions of the tropics

PRACTICAL NOTES

Inherited Tendency to Hemophilia—Dr Sadler, in the *Birmingham Medical Review*, reports a family having marked hemorrhagic tendency in two generations The father of the family died in 1895 of senile decay, the widowed mother is 60 years of age and in fair health She has had sixteen children, three of whom died from infantile complaints in the first few days of life The remainder comprises eight boys and five girls, the eldest of whom (a boy) at the age of 3 years, when apparently in perfect health, fell and bit off the tip of his tongue, the bleeding could not be stopped, and death occurred on the fourth day The next two sons and their children have not shown any tendency to the diathesis, nor has the fourth son The fifth son died at the age of three months, from "sun stroke" The sixth son was noticed to become bruised very easily at the time of his first attempts to walk When he was nearly 7 years of age the cutting of a tooth led to hemorrhage which proved fatal after a week's duration The seventh son, now aged 12 years, has never bled nor bruised The eighth boy early developed the tendency to bruise, but it is diminishing year by year He has had several troublesome attacks of epistaxis The joint affection of hemophilia first showed itself in him at the age of 3 years He has had repeated attacks since, and they always begin suddenly in the night The well known fact that the girls of the family do not themselves exhibit the hemorrhagic tendency, but that they transmit to their male children, appears in the present instance Both the first and second daughters have always been perfectly healthy, they are married, and have each had two boys three of these children are alive and present marked hemorrhagic symptoms The remaining one died at the age of 3 years from a combination of epistaxis with bleeding from the ears and mouth—London *Lancet*

Removal of a Bullet from the Body of the Axis after its Localization by Skiagraphy—In the *Intercolonial Medical Journal of Australasia*, Dr E Bird has published a case of this novel operation, which certainly could never have been carried out without the aid of skiagraphy The operation was performed more than three months after the injury, at the earnest solicitation of the patient, who suffered a good deal from deep cervical pains on the left side and stiffness of the neck A three inch incision was made along the posterior border of the sternomastoid muscle in order to gain access to the lateral aspect of the second and third cervical vertebræ The dissection was continued until the descending fibers of the first bundle of the levator anguli scapulæ were well defined in their upper two inches The great vessels and nerves were held forward and search made for the bullet It could be neither seen nor felt, but the transverse process of the axis was in advance of the next On holding the pharynx forward the dark bullet was seen buried in the body of the axis Bone had to be snipped away before it could be extracted, recovery followed

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, 100 Washington St Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor* and all communications relative to the business of the JOURNAL proof sheets returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

SATURDAY, SEPTEMBER 3, 1898

THE MUSTERING OUT OF THE VOLUNTEERS

When volunteer troops are to be mustered into the service of the United States, the one point of interest is the physical examination by the medical officer or medical examining board If the physical condition of the candidate for military service is such as to enable him to pass this examination successfully, the remainder of the process is easily accomplished, but in the mustering out of volunteer troops there is necessarily more of what is usually called red tape by those whose cerebral masses are incompetent to understand the details needful to bring a complicated piece of business to a successful conclusion in the simplest way The debtor and creditor side of the sheet between each officer and man of a command and the United States Government must have each entry accurately specified, so that when a last payment is made by the paymaster, a balance is effected and the contract between the soldier and the Government is dissolved Officers responsible for property have to turn it over to designated officers, obtaining in return from the chief of that particular supply department a certificate of non-indebtedness and enlisted men have to turn over arms and equipments in good condition The greatest care has to be taken in making up these muster-out rolls When finished they are submitted to a board of officers who compare their statements with the statements on previous muster rolls, and clothing account-books to ensure their absolute correctness in every respect The command is then sent to its state or regimental rendezvous to receive its final payments and be mustered out But here a new and very valuable piece of red tape has been introduced by the recent instructions to mustering officers issued from the office of the Adjutant-General of the Army This new departure is a piece of wisdom inculcated by the experience of our Bureau of Pensions since the close of the civil war In the language of the instructions just cited "To facilitate the settlement of pension claims that may be made on account of disability incurred in the United States service and to protect the rights of persons who may be entitled to the benefits of the pension laws as well as to guard the interests of the Government, it is ordered that a thorough physical examination be made of all officers and enlisted men of volunteers, except general officers and officers of the general staff, immediately prior to their muster-out of service or discharge " Each officer and enlisted man has to sign a declaration as to his physical condition, which is then verified by examination by a medical officer of the regular army whenever the services of such an officer are available, and when not, then by a medical officer of volunteers not belonging to the organization of which the officers and men to be mustered out are members If any person under examination claims to have a disability of which the medical officer can find no evidence, or to have a disability incurred in the line of duty, whereas the medical officer is of opinion that it was not so incurred, a board of three medical officers will be convened by the Adjutant-General to make a full report on the case, and if the members of the board fail to agree, a separate minority report will be made by the dissenting member The physical condition of every soldier at the time of his muster-out will thus be a matter of record, and the work of the Pension Bureau in the future will be materially reduced and simplified Had such an examination been made at the close of the civil war, the list of disabled pensioners would now be much smaller than it is by the exclusion of all those cases in which the evidence was defective and the benefit of the doubt given to the soldier

THE DUST CONVEYANCE OF TYPHOID FEVER

The spread of typhoid fever in the various military camps during the present war has become so serious a matter as to call for a most thorough investigation. it certainly was not anticipated and its occurrence will have to be accounted for It is naturally to be assumed that the camp sites were, for the most part, selected with reasonable care, and with at least the ordinary amount of sanitary precaution usual in such selections, under the oversight and with the consent of the Army Medical Staff There may have been exceptions, but this certainly should have been the rule Allowing fully for the careless habits of volunteers, the spread of typhoid seems t[illegible]ve be[illegible] excessive, and s[illegible] then th borne contamination would seem necessary to account for it It is be presupposed that, with the oversight of medical authorities and the generally diffused information in regard to the subject, any direct contamination of the sources of drinking water would have been avoided so far as possible, and if other methods of diffusion of typhoid can be invoked it may simplify the investigation materially, and we look with interest for the report of the very competent board selected by the Surgeon-General[1]

In a paper read before the British Medical Association, July 30, in its Section on State Medicine, Dr JOHN ROBERTSON, medical health officer of Sheffield, on "Soil as a Factor in the Spread of Certain Diseases," maintains that, while the water carriage of typhoid infection is important, the attention given to it has obscured the relatively still more important subject of dust- or filth-borne typhoid He has studied the subject carefully and finds that in over 80 per cent of urban cases the theory of water or milk infection will not suffice to account for the occurrence of the disease He finds also that the typhoid fever dies out quickly in grass covered areas, that when planted beneath the surface it has a tendency to extend upward rather than downward, and that it is capable of living and multiplying in the ordinary surface soil The transference of the germs from the soil to man is made, he feels assured, under certain conditions, chiefly through the medium of aerially carried dust

If we consider fully the conditions of some of our military camps, situated in a warm southern climate, where northern grasses can hardly be said to abound, and where such grass-covered areas as existed would soon be trampled out, occupied by inexperienced volunteer troops who naturally are ignorant and reckless as regards sanitary matters, and whose officers have their ideas of control and precaution in these respects yet to be formed, it is not difficult to suppose conditions that will fully account for the typhoid epidemic that has apparently existed At least this is true if we accept Dr ROBERTSON's conclusions, and they seem reasonable

Another point which he makes that is worthy of notice here, is the influence of ground-water, which had been already noticed by VON PETTENKOFER Dr ROBERTSON finds that typhoid is more liable to be endemic in regions where the ground-water is near the surface This, in connection with unsanitary local usages, such as are likely to prevail in camps, might have, it would seem, also an important influence With a surface soil impregnated with typhoid germs working toward the surface, and with grass wanting or trampled out, we have the most favorable conditions for the aerial transmission of disease and the winds, which should be a purifying ventilation, may thus become conveyers of pestilence

In those cases where the camps are supplied from artesian wells, the question of the height of the ground water can be of no possible consequence as regards direct infection by drinking water, but it might still have its influence as regards infection by the medium of dust

The character of soils in relation to disease is certainly an important subject, and one that has a special significance in a point of view of military sanitation In an active campaign in respect to fixed posts, where permanent sanitary conditions can be secured, it may be of less importance than in the case of temporary encampments for organization, like those of Chickamauga or Tampa, but in such the attention given it can hardly be overdone It is a possible thing that some phases of this particular question have been too much overlooked in our recent military operations In any case, the question of the propagation and carriage of the infection of such diseases as typhoid by the agency of the soil is one that should receive attention

THE SEVENTH ARMY CORPS AT JACKSONVILLE, FLORIDA

At this time when we hear so much of the prevalence of typhoid fever in the camps of our volunteer troops all over the land, it is gratifying to find satisfactory reports coming in from some quarters The camps at Jacksonville, Fla, are said to be in excellent condition, with few cases of typhoid in the division hospitals, and all these imported cases The water supply is from artesian wells, 800 to 1000 feet deep It is saturated when fresh with sulphuretted hydrogen gas, which speedily escapes on exposure to the air The hospitals are well provided with everything required, and the three division ambulance companies and the reserve ambulance company are thoroughly organized, fully equipped and in good running order The personnel of the hospital corps consists of 75 medical officers, 75 hospital stewards, 30 acting hospital stewards and 550 privates Lieutenant-Colonel L M MAUS, is Chief Surgeon of this Corps

RETINAL HEMORRHAGE

With the passing of the ophthalmoscope from the exclusive use of the oculist, the cases and causes of hemorrhage into the retina have greatly multiplied The underlying etiologic factors have become of interest to all, regardless of specialism, for the affection may occur in the practice of the surgeon and gynecologist as well as in that of the oculist and the devotee to internal medicine It may come without warning and indeed without apparent sufficient justification, or cautions in the way of constitutional disease may have existed for years It is no respector of age, nor are either of the sexes favored to any extent, for an increase on the one hand due to obstetric and gynecologic causes is equalized on the other by the greater prevalence of arteriosclerosis and injuries among males In size it may be barely discernible or may involve the retina in its entirety There may be but one spot, or the hemorrhages may be so numerous as to leave little more than spaces between them to show that they are separate and distinct Multiple hemorrhages may involve the periphera alone, may surround the optic disc, or invade the region of the macula lutea It will be remembered in the anatomy of the retina that the larger vessels lie in the layer of nerve fibers, while the capillary vessels are contained for the most part in the layer of ganglionic cells and in the inner molecular layer It follows from this that hemorrhage into the nerve-fiber layer appears superficial (to the ophthalmoscope), large, and as a rule striated, from the peculiar and characteristic course of the vessels in this area Occasionally the hemorrhage may be so near the surface and in such quantity as to rupture through the internal limiting membrane and involve the vitreous The age of the hemorrhage influences its color Fresh hemorrhages are of a deep red in comparison with the rest of the field, when older, evidences of decolorization are present, sometimes irregularly placed, more often around the periphera, forming a complete whitish investment Rarely the color may be entirely lost, nothing but a white patch remaining Whitish spots dotted here and there with masses of black pigment are not infrequently the only remnants of an extensive hemorrhage

---

[1] This board consists of Surgeon Walter Reed, U S A and Surgeons Shakespeare and Victor C Vaughan U S Volunteers

Leaving for a time the consideration of trauma in the production of retinal hemorrhage, the remaining cases can be traced to the circulatory system, either the blood itself or the vessels A most common cause is the rupture of a blood-vessel weakened in some way by disease, either by the formation of miliary aneurysms, as in syphilis, or by the production of arteriosclerosis The pipe-stem artery, no matter what the cause of its presence, be it Bright's disease, syphilis, chronic lead poisoning, alcoholism or what not, is always a source of danger and the retina which can offer but slight protection to the vessels contained within its various layers, is often a seat of rupture Not only in the slow, chronic, interstitial variety does Bright's disease bring about hemorrhage, but in that acute form known as hemorrhagic nephritis hemorrhages may occur There is one point of difference in the chronic disease the hemorrhages are superficial and, following the course of the vessels, are striated, forming the well-known "flame-shaped hemorrhages," while in the acute variety the hemorrhagic spots are large and irregular

Anything preventing the easy exit of blood from the globe, may, by overfilling the vessels behind, cause their rupture, especially if such an obstruction [illegible] been of long duration Thus local diseases of the ey as tumors, retinitis from whatever cause, glaucoma from whatever cause, myopia of high degree, thrombosis and embolism especially when involving the central artery of the retina, may be the underlying factor, as well as obstructive heart disease, especially mitral lung disease as chronic interstitial pneumonitis, tumors, or any other cause preventing a free flow of blood through the lungs While glaucoma itself may act as an exciting cause, it must be confessed that hemorrhage is more apt to follow a sudden diminution in the ivory hardness of the globe, in other words with the sudden lessening of the intra-ocular tension, as in an iridectomy for glaucoma, the support given the retinal vessels transmitted through the vitreous, is rapidly withdrawn, and rupture of these vessels readily takes place, particularly if arteriosclerotic changes have supervened

It is, however, in the diseases in which the blood itself has undergone changes that the larger proportion of cases occur These changes may be hydremic in character or result from the presence of deleterious, poisonous substances, but whatever the cause, the nutrition of the blood-vessels suffers, small areas of fatty degeneration form, and but slight traumatic causes may bring about rupture Such changes in the nutrition occur in constitutional affections, where fatty degenerative effects are common, diabetes, scurvy, septicemia, pyemia, purpura and in the acute poisonings where several days lapse before the fatal termination, as by phosphorus The blood diseases proper are complicated by hemorrhage into the retina It is not too much to say that in a majority of the cases of leukemia and pernicious anemia, retinal hemorrhages will be found, that are usually multiple in these diseases, often large, and as a rule irregular in outline Chlorosis and the simple anemias may all afford a complication of a similar nature and such cases are not infrequently mistaken for pernicious anemia

The affection is of interest to the gynecologist in that occasionally in amenorrhea, sudden blindness supervenes about the time of menstruation, were such a function going on, ophthalmoscopic examination reveals retinal hemorrhage without apparent cause This is then explained as an example of vicarious menstruation, and as in several reported cases of amenorrhea, fresh hemorrhages have occurred with each monthly interval, that explanation is probably correct in obstetric practice, retinal hemorrhages sometimes occur during the pregnancy, without apparent cause, though they are thought to be due to some change in the blood itself During delivery, efforts at expulsion producing cerebral congestion in a perhaps already weakened vessel, account for not a few cases New-born infants are especially susceptible to this trouble, but, rem [illegible] com- absorpt [illegible] involve the globe itself, as in a penetrating stab wound or a blow upon the ball without rupture, or an injury in the neighborhood, as a fracture of the base of the skull may occasion the same result The operation of iridectomy has this troublesome affection for one of its most dangerous complications, especially when the eye is glaucomatous and the patient well advanced in life When all is done and said, however, there still remains a fair proportion of cases in which no cause can be determined, the individual being in apparently perfect health

CLINICAL TEACHING

An inevitable change that must come in medical teaching is an extreme predominance of clinical and laboratory teaching over the didactic lecture The student can learn from lectures by able men, and much is unqestionably impressed upon the student's mind in this way alone, but aside from the practical experience of the lecturer and certain details of application which he can give, the student learns nothing that he can not gain from his text-book on the subject Furthermore, he loses as a rule a large part of the lecture by attempting to take notes, and no mind possesses the phenomenal ability to remember without notes a detailed series of lectures on a single subject, to say nothing of an attempt to retain lectures on many subjects At the end of one hour this student has a mass of notes, that are bad, as a rule, and an indefinite idea of the subject In clinical teaching the professor, again a man of experience in details, is in the presence of an actual case of the disease under description The disease is presented to the student as he will meet it in practice and his picture must be a more complete and lasting one than any that could be formed from a didactic lecture The value of clinical methods of teaching would seem an established fact and any argument in favor of it unnecessary, yet it does seem that the faculties of various colleges need to be reminded that their curriculum insists upon attendance at lectures and leaves the clinics to the option of the student The option regularly results in the cutting of clinics, or it results in his choice of the gynecologic clinic where his erotic desires are stimulated Furthermore, they need to be reminded that he is required to attend surgical clinics at some large hospital, where he wastes his time by observing an operation he will never perform or by being so far distant that he loses the detail In any out-patient department there are cases of surgery, medicine, skin diseases, etc, that he may handle, question, diagnose and, what is very important, follow to the termination of their illness These are the cases that will develop in him a distinctly medical mind and a clinical eye for observation By far too many students leave college today with the exact means of diagnosis impressed upon them to the exclusion of clinical symptomatology and unless furnished with the facilities for the Widal test are totally incapable of making a diagnosis of typhoid It seems imperative that such a condition should be changed and the out patient clinical work be required, if not made predominant, in his course A satisfactory examination in physical diagnosis and clinical treatment should be as necessary for a degree as a satisfactory paper in medicine or surgery The college must assume that the majority of its students will enter practice without hospital training and this means that he begins his professional career heavily handicapped by having no clinical pictures of disease, and especially handicapped when it is remembered that in the American perception and memory, sight represents four and hearing one

THE PURIFICATION OF SEWAGE BY BACTERIOLOGIC METHODS

The London County Council has lately undertaken a study of sewage and its purification by bacteriologic methods Experiments on the changes in crude London sewage by its filtration through coke are to be conducted at the outfall at Crossness Pending the construction of the filter and the completion of other arrangements, Dr A C HOUSTON, the bacteriologist who has been assigned by the Council to co operate in these investigations, has made a careful bacteriologic study of the raw sewage, preparatory to the special inquiry into the changes brought about by the micro organisms in the filterbeds which are designed for its purification The results of Dr HOUSTON'S work have been published by the Council as the first of a series of reports on the "Filtration of Sewage" The work was done in the Public Health Laboratory of St Bartholomew's Hospital, and thanks are accorded to Dr KLEIN "for advice and help of the greatest value" Samples were collected in sterilized glass-stoppered bottles, and cultivations were made on the day of collection Gelatine plates were used in determining the total number of bacteria The rapid liquefaction of the gelatine produced by the liquefying bacteria in sewage was found to be a decided disadvantage, but with a suitably diluted sewage and with observations made from day to day, it was not difficult to obtain plates with colonies sufficiently advanced in their growth and sufficiently numerous to allow of their being counted with accuracy, even when rapidly liquefying species were present From 0 1 to 1 0 c c of a liquid consisting of crude sewage diluted with 10,000 times its volume of sterile water was used in the cultivations, which were conducted at 20 degrees C When agar agar was used the results were too low and the differentiation of species difficult The number of colonies found in 1 c c of sewage varied from half a million to seven million, average about four million Spores were estimated by adding 1 c c of diluted sewage (1 10) to 10 c c of melted gelatine in a test tube, heating to 80 degrees C for ten minutes, and then pouring into a Petri's capsule The average number of spores in 1 c c of sewage was about 350 Liquefying bacteria were estimated from the ordinary gelatine plate supplemented by surface plate cultivations The number of these was always found to be large—about 400,000 per cubic centimeter It is held that their presence has a bearing on the ability of sewage to cause the liquefaction of its own solid or suspended matters

In discussing the search for special micro-organisms the B enteritidis sporagenes of KLEIN is given prominence A minute quantity of sewage is added to 15 c c of freshly prepared sterile milk, contained in a test-tube, which is then heated to 80 degrees C for ten minutes, cultivated anaerobically by BUCHNER'S method and incubated at 37 degrees C When B enteritidis is present the casein is precipitated, the whey remains nearly colorless, and there is a marked development of gas A guinea pig inoculated with 1 c c of the whey dies within twenty-four hours with typical enteritic lesions "If sewage," the report states, "be regarded as the most frequent and dangerous source of the pollution of natural waters, and if, as seems to be extremely probable, it is found that the B enteritidis is not present in pure waters, it is obvious that apart from the pathogenic character of this anaerobe, we are here dealing with a bacteriologic method of detecting contamination with sewage, which excels in delicacy any chemical process known As the life history of this micro organism becomes more fully known the bacteriologist may not improbably be in a position to condemn a water for drinking purposes, by merely considering the results obtained in his examination for this particular organism "

The B coli communis is found in London sewage in large numbers, together with many which can be differentiated only by subcultures on a variety of media The typhoid bacillus was sought for in surface phenol gelatine, and in potato gelatine plates and the diphtheria bacillus in ascitic agar plates incubated at 37 degrees C , but the occurrence of these two micro-organisms in sewage in numbers sufficiently great to afford even a faint hope of their isolation must be an event so rare that it is probably a waste of time, according to Dr HOUSTON, to specially search for them when more practical and more immediately useful work claims attention In the London sewage protean forms were very abundant, and spores of B mycoides, B subtilis and B mesentericus were usually present, but Sarcinæ, yeasts and moulds were rare

The report is handsomely illustrated by plates showing the gross and microscopic appearances of the micro organisms described The progress of this inquiry by the London County Council will be watched with interest by health officers and municipal authorities, in the hope that in its developments an answer may be suggested for the troublesome question, what is to be done with our sewage ?

THE PENSION PROBLEM

For years the pension problem has been an embarrassment to the Government, and at the close of the pressnt hostilities the question may assume greater proportions With the wisdom born of experience, plans of mitigation have already been devised to meet prospective difficulties Throughout the late Civil War the cry was against "red tape" as being a cunning art of procrastination, and not much time was bestowed upon records The medical department of the period was supposed to be sufficiently occupied with the sick and wounded in the gross Persons were classified into cases, and thus this system, although of value as a contribution to medical history, was useless in identifications Civil work was also neglected, principally on account of items absent from the blanks Information was not expected and therefore not given Besides, military activities due to a sudden expansion of the army were in the ascendant, levies of troops increasing in number at each call were more frequent, and the outcome of the war was at the least quite uncertain Pensions, likewise, were more lavishly promised, and provisions for liquidation of claims were rather on a haphazard scale As in life, individuals degenerate into records, so in the cases under consideration, what wonder that there should be delays, disorder, frauds and denials of justice? In the language of a war department official "the chief difficulties have been in the obtaining and sifting of testimony after late determinations " For more than thirty years an army of examiners, regular and special, has been maintained at a great outlay, since a government, like a bank secretary, ever pays upon mere sight of the draft Beyond a doubt a nation's gratitude is desirable to the claimant, but somehow the much-referred-to "unscrupulous attorney" spoils the chances of the worthy and gains but little in the way of a pittance for his easy-going client armed with his flawless affidavit, in too many instances entirely innocent of the fatal element of truth

We have been assured that our new pension list, according to the most accurate calculations, will closely crowd about 3000, owing to the new warfare and the triumphs of modern surgery But we are also told that over 600,000 old applications are pending, which include original pensions as well as increases accrued and new disabilities With all the humane tendencies of the government and all the liberal provisions against disaster, proof of worthiness is a necessity, and the applicant must consume a deal more of time than he expected The work to be done is practically indexing his own records so that they may lighten the labor of the searchers, in other words, the card system of libraries with duplicates as a provision against accident, the same, as a matter of detail to be edited by a chaplain or company secretary for the sake of conciseness and smoothness · diction These hints are given out

Malingering.

WASHINGTON, D C, Aug 24, 1898

To the Editor —Apropos of the communication on "Malingering" (p 423, August 20), suits for alleged malpractice are indeed to be deprecated, and it behooves the profession everywhere to stand together in resisting the attacks of the ignorant and the malicious, whether they be directly from the laity or, as is so often the case, inspired by more or less unprincipled and over zealous "shysters" of the legal profession On the other hand, when, as in the case cited, the medical practitioner adopts such questionable methods, does he not but reap the penalty of his folly? That a physician should consent "nearly every day, to make some kind of an application to the uterus" of a pronouncedly hysteric woman of neurotic history, "more to satisfy her than for any good it did," is of the very essence of charlatanry There seems to have been no question as to the diagnosis, the symptoms noted would be most natural under the conditions described The daily diddling, under the guise of legitimate operative procedure, could accomplish nothing but an aggravation of the patient's erethism, pampering to her depraved sensibilities Of course, the patient is strong, robust, healthy, and active," "since he quit" practicing such instrumental masturbation! Such treatment, or rather such abuse of the perverted sexual instinct of a hysteric, smacks of ignorance born of laziness, if no worse, but, by the defendant's own admission, he deliberately set about to deceive his patient, "to satisfy her intense desire that he should use powerful remedies to kill her cancer," which he knew she had not Surely, the "reputable firm of lawyers' could find no better brief to submit in behalf of their client than this outrageous confession Faithfully yours,

MURRAY GALT MOTTER, M D

ASSOCIATION NEWS

Some Suggestions Regarding the American Medical Association —The large number of physicians attending the annual convention of the American Medical Association are certainly entitled to individual consideration It is, therefore, proper for the benefit of the scientific sections to have only those papers read which are practical and which can bring out good discussions, or those based upon practical research and investigation There can be no question that either there is mismanagement in some Sections or that special favoritism is bestowed on a few influential friends Our attention is, however, directed to an abuse which calls for an executive investigation, viz That certain men send titles of papers to several sections—in some instances they announce papers in three different sections, in most instances merely to see their names in print or else to see how often they can find their names printed in a single program In one instance a gentleman was given preference on the program and other papers postponed to enable this bright individual to wander from section to section and give "scientific" orations and expound new ideas, based on experience of long standing This is radically wrong While there can be no objection to discussing papers of especial interest in the various sections, especially so if invited to participate, we feel that it is radically wrong to permit some men to monopolize various sections and crowd equally prominent men It can only add to the dignity and scientific value of each particular section if each paper, or rather if the abstract was carefully scrutinized and eliminated if not found desirable This would not only encourage good work, but would stimulate those men who boast that anything is good enough for the American Medical Association —*Medical Times and Register*, August 13

SOCIETY NEWS

Tennessee Health Officers' Association —This body held a three days' session at Nashville, Tenn, ending August 16 In the election of officers, Dr W S Nash of Knoxville, was re elected president and other officers chosen as follows First vice president, Heber Jones of Memphis, second vice president, Charles E Lones of Knoxville, third vice president, Larkin Smith of Nashville, secretary, H C Chance of Tazewell, advisor and superintendent of the veterinary division of the association, H D Fenimore of Knoxville

Canadian Medical Association —At the twenty first annual meeting of this Association, held at Montreal, August 18, 19 and 20, the following officers were elected President, Dr Irving H Cameron, Toronto, vice presidents, Prince Edward Island, Dr J McLeod, Charlottetown, Nova Scotia, Dr Kirkpatrick, Halifax, New Brunswick, Dr L N Bourque, Moncton, Quebec, Dr Jas Bell, Montreal, Ontario, Dr J A Williams, Ingersoll, Manitoba, Dr R S Thompson, Deloraine, Northwest Territories, Dr Lindsay, Calgary, British Columbia, Dr P J Tunstall, Vancouver, general secretary, Dr F N G Starr, Toronto, treasurer, Dr H B Small, Ottawa, publishing committee, Drs A D Blackader, J L Dawson, W W Young and the general secretary and treasurer, by laws, E C Parne, Wyatt Johnston, Jas Bell, E R Dickson, G S Ryan, W W Dickson, M. Beausoleil and the president and secretary

Health Officers and Sanitarians in Illinois are invited to the next meeting of the Auxiliary Sanitary Association of the Illinois State Board of Health, which will be held in the Capitol Building at Springfield on Sept 26 and 27, 1898 The object of this meeting is to discuss matters of interest to those engaged in sanitary work, such as the prevention and restriction of communicable diseases, the regulation of systems of sewerage and public water supplies, the drainage and sewerage of villages, the legislation necessary to promote sanitation throughout the State, etc, and to establish close relationship between the State Board and local officials A program of the papers to be read will be sent to any who make request, by the Secretary, who will also gladly answer any inquiries The Illinois State Fair will be held at Springfield, September 26 to October 1 Those who attend the convention will have an opportunity to also visit the Fair on the days when the most attractive programs will be presented, and the railroads have agreed to sell tickets to all attending the Fair at one fare for the round trip from any point in the State J A Egan, M D, Secretary Illinois State Board of Health, Springfield

Association of American Medical Colleges —*Decision of the* Judicial Council, denying the right of the Medico Chirurgical College of Philadelphia to resign *its membership*

The Council decides that the Medico Chirurgical College of Philadelphia is now, and has been continuously since 1891, a member of the Association of American Medical Colleges, in full fellowship It signed the Constitution and By Laws and participated in each annual meeting, *including that of* 1898, thereby assuming the obligation of honor to maintain and observe all the provisions of the constitution

Article III, Section 3 of the Constitution, which the said Medico Chirurgical College voluntarily pledged to observe, says "Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter, shall have attended at least four courses of medical instruction, each course of at least six months' duration, no two courses of which shall have been in the same calendar year"

Section 6, Article III, prescribes the conditions on which credits for one year of time, in the four courses may be extended to certain persons whose claims for exemption are clearly defined

Section 7, Article III, states that, "Members of this Association may confer the degree of Doctor of Medicine, during the year 1898, upon students who have attended three courses of six months' duration each, each course shall have been in a separate calendar year"

The Judicial Council of the Association of American Medical Colleges has repeatedly decided that the constitutional requirement of four courses in 1899 and thereafter must be construed to begin Jan 1, 1899, and these decisions have been unanimously adopted by *the aid of the votes of the* said Medico

Chirurgical College participating in the general sessions of the Association It is impossible that the said Medico Chirurgical College, an institution of high character, could have promised any student to descend from the scale of honor, and to hold down the standard below the requirements it solemnly pledged to observe in 1899 and thereafter

The AMERICAN MEDICAL ASSOCIATION, at Detroit June, 1892, unanimously demanded of all the colleges in the United States the adoption and observance of a standard of requirement for the degree of Doctor of Medicine, which should in no manner fall below the minimum standards of the Association of American Medical Colleges At Denver, on June 9, 1898, the AMERICAN MEDICAL ASSOCIATION unanimously resolved to hereafter deny the right of membership to any professor or other teacher in any medical college which confers the degree of Doctor of Medicine on conditions below the published standards of the Association of American Medical Colleges after Jan 1, 1895 Those receiving the degree on such conditions are likewise barred It is clear, therefore, that the College Association must maintain its own published requirements, as these are conditions which shall determine the qualifications of membership in the AMERICAN MEDICAL ASSOCIATION The Association of American Medical Colleges can not concede to any one of its members the privilege of resigning to fulfill a pledge made as a breach of faith

It is the judgment of the Council that the resignation of the college can not be accepted, and that the presence of Professor LaPlace as the authorized delegate, and Professor Shoemaker as an associate, and their participation in the general sessions of the Association of June 6, 1898, directly contradict the statements of Dean Egbert in his letter of resignation

Mississippi Valley Medical Association—The following is the preliminary program for the meeting at Nashville, October 11-14, 1898

Why I have Abandoned the General Practice of Vaginal Hysterectomy B Sherwood Dunn, Boston, Mass

Tonsillitis or Quinsy, Causes and Treatment J A Stucky, Lexington, Ky

Pichi H W Whitaker, Columbus, Ohio

A Few Practical Points in the Treatment of Posterior Urethritis A Ravogli, Cincinnati, Ohio

The Neuro Hypothesis of Rheumatoid Arthritis Frank Parsons Norbury, Jacksonville, Ill

Diphtheria and its Logical Treatment A M Osness, Dayton, Ohio

Varicocele F E Kelly, LeMoille, Ill

A Plea for Pelvic Peritonitis and Cellulitis F F Bryan Georgetown, Ky

Syphilis John M Batten, Pittsburg, Pa

Gonangeiectomy and Orchidectomy for Hypertrophied Prostate in Old Men Geo W Johnson, Dunning, Ill

Wounds of the Lachrymal Apparatus, Report of Operation for Restoration of Canaliculi Obliterated by Traumatism Geo F Keiper, Lafayette, Ind

A Consideration of the Limit to Operative Gynecology Shelby C Carson, Greenboro, Alabama

The Relations of the Gynecologist and the Neurologist W H Humiston, Cleveland, Ohio

Intermingling and Changing of Type in Diseases W Gaston McFadden, Shelbyville, Ind

Mercury and Its Action William F Barclay, Pittsburg, Pa

The Diagnosis of Gonorrhea in Women J Riley Eastman, Indianapolis, Ind

Sub Periosteal Removal of Caries from the Pelvic Basin, with the Report of Cases S E Milliken, Dallas, Texas

Complete Inspection of the Rectum by Means of Newer Mechanical Appliances Thos Chas Martin, Cleveland, Ohio

Hydrotherapy in Stomach Diseases Geo D Kahlo, Indianapolis, Ind

Surgical Treatment of Infantile Paralysis Alex C Wiener, Chicago

Suprapubic Cystotomy vs Perineal Section James M M Parrot, Kingston, N C

Report of Cases in Obstetrics with Complications R C Pratt, McKenzie Tenn

How Should We Treat Typhoid Fever° T Virgil Hubbard, Atlanta, Ga

Interesting Surgical Cases M Goltman, Memphis, Tenn

The Relationship between the Genito urinary Tract and Rectum, with Special Reference to the Female John L Jelks, Memphis, Tenn

A Clinical Contribution to Ectopic Gestation W W Taylor, Memphis, Tenn

The Bicycle from the Medical Standpoint I N Love, St Louis

Surgical Treatment of Pus in the Pelvis Jos Price, Philadelphia, Pa

Operations on the Mastoid, When and How Performed Andrew Timberman, Columbus, Ohio

Arthritic Diathesis R A Bate, Louisville

Diagnostic and Therapeutic Uses of Tuberculin Chas W Aitken, Flemingsburg, Ky

Some Pathologic Conditions of the Ovaries and Adnexa Causing Pain G W Halley, Kansas City, Mo

American Association of Obstetricians and Gynecologists—This Association will hold its eleventh annual meeting at Pittsburg, Pa, Sept 20, 21 and 22, 1898 The following program is announced

President's Address, Charles A L Reed, Cincinnati

Septic Infection of Ovarian Cystoma, Charles Greene Cumston, Boston

Recent Experiences with the Alexander Operation, H E Hayd, Buffalo

Nursing in Abdominal Surgery, Joseph Price, Philadelphia

Carcinoma of the Breast, W F Westmoreland, Atlanta

Operative Technique for Intraligamentous Ovarian Cystoma, D Tod Gilliam, Columbus

Organization of Major Operations in Private Practice, W G Macdonald, Albany

Explanation of the Character of the Temperature in Appendicitis, Robert T Morris, New York

Pathologic and Clinical Phases of Gall Stone, A H Cordier, Kansas City

Some Facts in Regard to Uterine Fibroids, H D Ingraham, Buffalo

Albuminuria Complicating Gynecologic Operations, Rufus B Hall, Cincinnati

Extrauterine Pregnancy with Specimen, Mature Fetus Borne Twelve Years, W J Asdale, Pittsburg

Surgical Treatment of Morbid Conditions Involving the Broad Ligaments, A P Clarke, Cambridge

Paper by Walter B Dorsett, St Louis

A Second Paper on the Surgical Treatment of Intussusception in Infants, with Cases, H Howitt, Guelph, Ont

Relation of Nervous Affections to Diseases of Female Pelvic Organs, B Sherwood Dunn, Boston

Ureteral Anastomosis, Geo H Noble, Atlanta

The Graver Forms of Nerve Disturbance due to Organic Changes in the Genital Organs, W H Humiston, Cleveland

Some of the Complications Following Vaginal Hystero Salpingo oöphorectomy in Pelvic Suppuration, F Blume, Allegheny

The Question of Intra abdominal Drainage, Edwin Walker, Evansville

Report of a Case of Double Uterus and Vagina with Pregnancy in one Horn, Excision of Vaginal Septum, F Blume, Pittsburg

Some Clinical Observations, Based on Over 100 Abdominal Sections for Ovariotomy, X O Werder, Pittsburg

Remarks on Methods of Hemostasis, with Demonstration, Walter B Chase, Brooklyn

Past and Present Surgery of the Gall bladder and Bile ducts, William H Myers, Fort Wayne

Treatment of Granular Erosion of the Cervix by Ligature of the Cervical Vessels, D Tod Gilliam, Columbus

Relation of Rectal to Pelvic Disease and to Nervous Disorders in Women, Joseph M Mathews, Louisville

Treatment of Endometritis, William A B Sellman, Baltimore

Tubercular Peritonitis, J B Murphy, Chicago

BOOK NOTICES

Diseases of Women A Treatise on the Principles and Practice of Gynecology for Students and Practitioners By E C DUDLEY M D Octavo, pp 637 Philadelphia and New York Lee Bros & Co 1898

Professor Dudley's work is the result of long years of study and observation and this fact must carry with it a certain authority The book fairly covers the field of gynecology, and is divided into five parts Part I is given to the general principles of gynecology, such as psychologic periods in the life of women, aseptic and antiseptic diagnosis, local treatment, major and minor operations, drainage and after treatment, relations of dress, Part II is given to inflammations of the female generative organs, including the pelvic passage, Part III to tumors, tubal pregnancy and malformation, Part IV discusses traumatisms, both nonpuerperal and puerperal, and Part V displacement of the uterus and other pelvic organs

The teachings of the author are sound and conservative, the illustrations are clear, many of them original, and the book as a whole constitutes a valuable contribution to the subject The author's personal contributions to gyneclogic literature have been extensive, and the resulting work may be taken as a finished product of his life experience

History of Yellow Fever, Indispensable Facts Pertaining to Its Origin and Cause, and Its Present Artificially Acquired Habitat, with Reasons Going to Show the Possibility of Its Complete Extinction from the Globe, Its Nature, Anatomic Characteristics, Symptoms, Course and Treatment, with an Addendum on its Twin Sister, Dengue, containing a Parallel Table of the Most Prominent Symptoms of each Disease By W L COLEMAN, M D Pp 141 Houston, Texas

This book comprises the results of forty years' active work in the South and personal experience in passing through several epidemics of yellow fever It is pleasantly written, and many of us will notice with pleasure the frequent reference to names of well known epidemiologists The anecdotes in the book are well told, and whether or not one agrees with the optimistic views of the writer in regard to the prevention and ultimate extinction of the disease, he will at least derive pleasure from a perusal of the book

A Guide to the Clinical Examination of the Blood for Diagnostic Purposes By RICHARD C CABOT, M D With colored plates and engravings Third revised edition Pp 452 Octavo New York William Wood & Co, 1898 Price, in cloth, $3 25

We have heretofore mentioned in terms of praise the appearance of successive editions of this estimable volume The present edition has had about forty pages of new matter added, in which is an account of Professor Oliver's tintometer and hemoglobinometer, new matter on the primary anemias and on leukemias, also a description of Muller's "blood dust" new observations on poisoning by alcohol, opium, corrosives and ptomains, on aneurysms, on paroxysmal hemoglobinemia and on cretinism The general plan of the book remains the same as heretofore It is indispensable for practitioners who desire to keep abreast of the newer methods of clinical diagnosis, and is wholly a credit to American medical literature

Laboratory Work in Physiological Chemistry By FREDERICK G NOVY Sc D, M D Second edition, revised and enlarged Pp 326 Ann Arbor George Wahr, 1898

This edition is, as stated on the title page, enlarged and revised, so much so as to almost constitute a new book Every medical student should receive laboratory instruction, and this work will be indispensable in the examination of food stuffs and the fluids and secretions of the body Indeed, modern physiology requires so much experimental work for its proper understanding that the intelligent reading of a modern text book is scarcely possible unless one keeps posted in the operations of the laboratory

Transactions of Forty eighth Annual Meeting, with Constitution and By Laws, of the Illinois State Medical Society, held in Galesburg May 17, 18 and 19, 1898 Pp 530 Ottawa Free Trading Printing house, 1898

This volume contains, besides a record of the proceedings, the addresses and papers read before the Society, list of officers, place of meeting, list of members, officers of sections and committees The Secretary is to be congratulated upon the early appearance of the transactions, the careful editing and excellent makeup We regret that the speeches at the annual dinner were not reported, but otherwise there is little room for criticism The papers are generally excellent and show a high grade of work

The Sanitary Institutions of the Imperial Government of Japan Paper Pp 103 Published by the Central Sanitary Bureau of the Home Department, Yokohoma, 1898

The five parts of this volume deal respectively with "The Organization of the Sanitary Institutions," "Institutions as to the prevention of Infectious Diseases," "Institutions for Vaccination," "Public Health Institutions," and "Medical Institutions" The arrangement and classification of the topics under these several heads is clear and the various chapters contain much information as to the sanitary institutions of Japan

Proceedings of the Association of American Anatomists Paper Illustrated Pp 142 Washington, D C 1898

This volume contains the proceedings of the tenth annual session of this Association held at Cornell University, Ithaca, N Y, Dec 28-30, 1897, and an appendix containing a list of members It also contains the Constitution, officers for 1897-98, a report on anatomic nomenclature, and various papers and discussions

NECROLOGY

Francis Walton Todd, M D , was born at Bardstown, Ky , April 17, 1816, and was educated at Illinois College, Jacksonville, Ill In March, 1838, he was graduated in medicine at Cincinnati College under the tutelage of Drs Drake, Willard Parker, Fash McDowell and Samuel D Gross, and in 1839 he went to Port Gibson, Miss , where he practiced his profession until February, 1847, when he joined the army of General Scott as an assistant-surgeon, and made the campaign to the city of Mexico After the close of the war he resided in New Orleans until the spring of 1849, when he went to Panama, and was employed by the chief engineer superintendent of the railroad, then building, to take care of his sick, which he did until the steamer *Panama* came around from New York, on which vessel he went to California, arriving at San Francisco June 4, 1849 For several years he resided at Todd's Valley, Placer County, and to the practice of medicine he added horticulture and viticulture in which he was successful, but the mines having become exhausted, and the population gone to other pursuits, together with his remoteness from market he gave away a property that had cost him a large sum and removed to Stockton, where he gave twenty years to medicine, except three years spent in Europe During this time he held, for several years, the office of member of the first State Board of Health, was a delegate to the International Congress in 1876 at Philadelphia, was one year the secretary, three years a vice president, and one year president of the State Medical Society of California, president of the Board of Health of Stockton, for two years president of the San Joaquin Society of California Pioneers, and as long as the Society existed was secretary of the San Joaquin County Medical Society Retiring at the age of 72 years, from a laborious practice, he sought ease in retirement at Coronado, Los Angeles, and other resorts Dr Todd was a mason and knight templar and died at Capitola, Cal , Aug 5, 1898, strong in the faith of the Christian religion

Lawrence S Smith, M D , major and surgeon of the First Regiment Penn Vol Infantry, died at sea, on the hospital ship *Relief*, August 17, of typhoid fever Major Smith was 32 years old, and since 1894 has been in general medical practice at 133 South Eighteenth Street, Philadelphia, Pa , devoting special attention to gynecology He was educated at the Cheltenham Military Academy, subsequently entering successively the College and Medical Departments of the University of Pennsylvania, from which he graduated in 1891, then serving eighteen months as resident physician, the time being divided between the Pennsylvania Hospital and the University Hospital From the latter he went to Germany, and studied at Goettingen for two years, At the outbreak of the war with Spain he was surgeon major of the First Regiment, and was mustered into service with that command at Mt Gretna While at Chickamauga he was ordered to Newport News, to accompany the Porto Rican expedition as surgeon of the First Army Corps, and contracted typhoid fever at Ponce

John F Morse, M D —On August 23 San Francisco witnessed the funeral of one of her ablest surgeons, John F Morse He was a native Californian, graduated from the old Medical College of the Pacific in November, 1878, and had practiced surgery in San Francisco almost continuously since that time For some years he was connected with what was then known as the Morse Clinic of the Cooper Medical College, the clinic having been established by his father A few years ago there arose a difference of opinion between Dr Levi C Lane, who controls the Cooper Medical College, and Dr Morse, which resulted in Dr Morse severing his connection with the clinic Dr Lane thereupon changed the name of the clinic from the "Morse Clinic" to the "Cooper College Clinic " Dr Morse shortly afterward was appointed chief surgeon to the German Hospital, which position he filled with eminent satisfaction up to the time of his death He was an intense student, a brilliant, clever and capable operator, a hard worker, and a man of sterling honesty No surgical proceeding or possibility, which offered the slightest prospect of relief for his patient, was too difficult or appalling for his deft fingers or his clear, cool thinking He was a member of a number of lodges and societies, and at the time of his death an active member of the Board of Health of San Francisco The funeral was held under the combined auspices of those various organizations Though his home and his work were in San Francisco, his name and his fame were confined to no City and no State in our country, nor to our country alone He died after an illness of about ten days, from cerebral hemorrhage following a collapse from overwork His life was a living illustration of the three factors which should actuate every physician Honesty, thoroughness, and persistent, indefatigable application

John S Griffin, M D , a pioneer physician and a public spirited citizen, who founded East Los Angeles, and whose sheep once roamed in thousands over his ranches in San Pasqual, now Pasadena, died at Los Angeles, Cal , August 21, aged 82 years Through the history of Southern California for the past half century runs the thread of his life He received his medical education at the University of Philadelphia, and practiced several years in Louisville, Ky , being appointed assistant surgeon in the army in 1840 After service in Florida, he was with General Kearney in 1846, when he entered Santa Fé at the outbreak of the Mexican War, going to San Diego, Cal , Dec 10, 1846

Joshua P Arthur, M D , Laredo, Texas, August 19, aged 58 years ——Harvey S Baker, M D , Bradford, Pa , August 17 ——C B Belt, M D., Boston, Mass , August 23, aged 51 years ——D W Boyd, M D , Yoakum, Texas, August 18 ——N Chapman, M D , Washington, D C , August 16, aged 58 years ——G A Henry, M D , Detroit, Mich , August 19, aged 35 years ——C M Hibbard, M D , St Louis, Mo , August 22 ——Caleb C Johnson, M D Hillsdale, Mich , August 28, aged 84 years ——W D Lonergan, M D , Rogers Park, Chicago, August 28, aged 57 years ——E G Moore, M D , Spring Valley, Ill , August 11 ——John Morehead, M D , Dixon, Ky ——John Borland Wallace, M D , Detroit, Mich , August 21, aged 48 years

PUBLIC HEALTH

Yellow Fever in the South—According to press dispatches of August 25, Dr Carter of the United States Marine Hospital Service, who has been stationed at Franklin, La , declares the case previously reported there as suspicious to be genuine yellow fever This is the second case reported at Franklin

Barbers Preparing a Bill—According to the *Chicago Record* of August 25, the barbers and some of their friends in the medical profession will prepare a bill to present to the legislature which, if it becomes a law will require barbers to disinfect all tools, towels, sponges, brushes and whatever articles may be required in the pursuit of their business Under this law nothing but strictly antiseptic barber shops will be allowed in Illinois The bill will provide that all barber shops shall be under the control of the State Board of Health and each pay a license of $10 a year The license shall only be granted after a thorough examination of the applicant s shop has been made and its sanitary conditions approved Each individual barber shall also pass an examination as to his knowledge of the trade and as to his knowledge of the use of disinfectants The barber shall also have worked at his trade a certain number of total cases in this country to 100. Of these 64 cases, the youngest was six months old, the oldest 2½ years. Four only were over eighteen months of age, and 35 from nine to thirteen months. Of 50 cases in which the sex was noted, 24 were girls and 26 boys. Of the 64 cases, 52 presented a definite gum affection. The gums were normal in 10 and in 2 the record was incomplete. From his tabulations he concludes that 1. The contention that there is no evidence that scurvy has been caused by sterilized milk must be given up. The evidence here presented is not considered conclusive, but it renders it highly probable that persistent sterilization of the food by boiling may produce scurvy. 2. It must even be admitted that scurvy may develop in nurslings.

Women in the Medical Profession.—The recent German Aerztetag or Congress of Physicians devoted one session to a consideration of this question, finally officially adopting the conclusions of Prof. Pentzold's address, "If women should enter the profession in large numbers which is however scarcely probable as long as the requirements are the same as for male students, and as long as no special schools are founded to facilitate their studies, the sick would not be materially benefited, it would prove no benefit, to say the least, for German universities and German science, it would detract from the dignity of the profession, and the public welfare would not be promoted thereby. For these reasons it is unwise for medicine to be the first of the learned professions to admit women."

Deligation of the Innominate Artery.—Dr. J. T. Lewtas (*Indian Lancet*, May 16) reports the successful ligation of the innominate artery for secondary hemorrhage following an injury to the subclavian artery due to the bursting of a gun. The man entered the hospital a month after the injury, complaining of pain and stiffness in the neck and shoulder. Alarming hemorrhage followed the removal of a flat piece of steel, and the man became unconscious from loss of blood. The operation was performed without an anesthetic, and the patient seemed in a hopeless condition. He rallied, however, and made a slow but satisfactory recovery, being able six months after the operation to earn his living as a field laborer and stating that his right arm is as strong and useful as his left.

The *Philadelphia Medical Journal* makes the above annotation, and adds that while the innominate artery has been deligated a considerable number of times, this case is believed to be the third successful operation.

Diphtheria of the Eye.—McCollum, writing on "Antitoxin in the Treatment of Diphtheria" (*Boston Med. and Surg. Jour.*, for August 18), mentions fifteen cases in which the sight would undoubtedly have been lost except for the heroic administration of antitoxin. In only one of those cases was there destruction of the organ, and this was in abnormal condition at the commencement of the attack. "When a diphtheritic membrane appears in the eye the effect of antitoxin on the membrane can be more carefully studied than when it appears in the pharynx. In some of these cases 2000 units were given as the initial dose, and this was repeated in six or eight hours, if there was not a marked improvement." Except in very young infants, he believes the initial dose should be 2000 units, and in severe cases 4000 units may be given, the more concentrated the better, as the possible source of danger *lies in the amount of fluid*, and not in the inherent property of the antitoxin.

The Artichoke as a Culture medium in Microbiology.—Bacterial cultures have been made on almost all vegetables but the potato and the carrot are the principal ones in daily use in bacteriology. M. Roger has, however, reported to the Society of Biology, at the July meeting, that *in his opinion the artichoke* possesses several advantageous qualities in this respect. Nothing is more simple than to prepare it for the purpose. After having stripped off the scales the thick part is cut up into little cubes, care being taken to preserve the fibers (foin). The pieces are placed in tubes plugged with damp wadding the fibers being uppermost, so that the culture medium is represented by *a fleshy mass surmounted by a sort of tuft*. When the wadding is inserted the whole is heated in an oven to 115 degrees C. for a quarter of an hour. In making the inoculation *the germs must be deposited at the point of insertion* of the flowers.—London *Lancet*, July 30.

Antitoxin Treatment of Tetanus.—Lund (*Boston Med. and Surg. Jour.*, August 18) reviews the treatment with tetanus antitoxin to date, and concludes that 1. The statistics show a diminution in the mortality, but the cases treated have as yet been insufficient in number, the reports too indefinite, and probably not all fatal cases included. 2. The more careful study shows less evidence that the antitoxin treatment, and not the mild course of the disease, determined the favorable course. 3. In the majority of instances the dose, especially the initial dose, has been too small. 4. The treatment demands further trial. 5. *Efforts to secure a stronger product* with a sufficiently large initial dose and at the earliest possible moment, directly into the blood stream will make it more effective. He believes that *for immunizing purposes antitoxin* has a valuable field, and the treatment should consist of Thorough disinfection of the primary focus by mechanical means, including, if necessary and practicable, amputation, the thorough local employment of such chemic antiseptics as have been shown to destroy both the bacilli and the toxin, symptomatic treatment by sedatives, etc., thorough diuresis, *intravenous injection of an amount* of antitoxic serum which shall contain at least 500 antitoxic units, at the earliest possible moment.

Hemorrage Following Tonsillotomy.—Zimmermann (*Archives of Otology* for August) says that tonsillotomy should never be performed in certain constitutional affections, as in hemophilic persons or those who for any reason have a tendency to bleed profusely, or in hypertrophy of the left ventricle, hemorrhage occurs more frequently in adults than in children. In acute inflammation it should not be performed, hyperemia being present and a greater tendency to bleeding. After the operation the patient should keep quiet, avoid alcoholics, not use his voice, not travel, and not eat solid food for several days. Gargling with cold water is good after the operation, but not for too long a time, as it may interfere with the formation of thrombi. After the bleeding ceases, dust the surface with iodoform mixed with tannic acid. In persistent hemorrhage, resort to the Paquelin thermocautery, or a thick probe made redhot. Cauterization not being successful, he grasps the bleeding spot with an artery forceps which he leaves in place for a while and then makes torsion. "In all cases of severe bleeding after tonsilotomy the patient ought to be kept in an erect position, so that by the resulting anemia of the brain he is apt to faint, as a spontaneous restraint of the bleeding has been observed in cases in which an attack of syncope occurred."

Anecdote Concerning Dr. William Pepper.—The *Philadelphia Medical Journal*, August 6, tells the following incident of his later life, tending to show the heroic temperament and habits of its subject. The writer says "We are enabled to put on record a pretty little incident that occurred within the past few months which is related in illustration of the character of the man. A visitor calling upon him found him asleep in his office. He opened his eyes and gave a cheerful though weary greeting. At this moment a boy brought in a letter. Without rising, Dr. Pepper read it and handed it with the attached slip of paper to his visitor with the remark, 'This is the sort of thing that is killing me.' When the visitor read the slip, which was *a check for* $10,000 for one of Dr. Pepper's numerous works of beneficence, he said, 'Most men would be made very much more alive by such work as this of yours.' 'Each endowment I get costs me so much life.' To the further ques tion why he should not prolong his life by working less intensely and constantly, he half contemptuously said, 'If the same work is done in ten years for which others take thirty, it is in reality doubled, and more than doubled' It was the public duty upon which his eye was ever fixed, and everything, even his own life, certainly his own selfish interest, must be sacrificed to the noble cause He might be called our greatest institution builder He was assuredly Philadelphia's best friend and greatest citizen"

The Fool on a Cycle—In spite of the object lessons which inquests on cylists give, and in spite of police prosecutions, the number of cycling accidents increases, while it is evident that the majority of the casualities follow upon reckless riding The most common cause of disaster is want of caution in descending hills The effort of the National Cylists' Union to prevent accidents by placing notice boards at the top of all dangerous hills is treated with contempt by many cylists, who regard such boards as a playful invitation to "coast" to the bottom In a recent inquest held at Hull, the coroner is reported to have said that if cyclists persisted in disregarding notices which were exhibited for their personal safety it might be necessary for the protection of the public to require all cylists to dismount on going down hills which were marked "dangerous," and to inflict a heavy fine in every case where the notice was disregarded We quite agree "Put a fool on a cycle and he will ride to destruction," makes a very good reading of an old saw, and describes a situation which we can regard with equanimity But when the fool on his way to his proper destination thinks well to smash into other people it is time to put a limit to his folly —London *Lancet*, August 6

The Histopathology of Herpes Iris—Dr L C Pardee in the *Bulletin of the Johns Hopkins Hospital* for July reports two cases of this disease, with the results of a close study of its pathology His report shows that the histopathology may be summarized as an acute exudative inflammation of the upper half of the corium, with dilatation of the superficial network of blood vessels and lymphatics (the latter being slight), accompanied by a considerable emigration of polynuclear leucocytes, which in one case became almost immediately disintegrated after leaving the capillaries of the papillæ The latter, as the process extended, became practically filled with nuclear detritus, and, by the confluence of neighboring papillæ similarly affected, the vesicle was formed This phenomenon of nuclear fragmentation does not appear to have been noted by any previous observer In both cases the vesicle was formed by the lifting of the entire epidermis from the papillary body, the former becoming compressed over the vesicle in Case 1 and in Case 2 appearing swollen and edematous, and showing more or less dilatation of the inter epithelial spaces and detachment of the cells of the basal layers of the epithelium. The contents of the vesicles were always the same, and consisted of coagulated serum, polynuclear and mononuclear leucocytes, occasional detached epithelial cells, strands of fibrin, and in Case 1 much nuclear detritis No infarcts of blood vessels and no hemorrhages were noted The sweat apparatus, hair follicles and sebaceous glands were unaffected

The Typewriter—Bizzozzero in Italy, and other foreign writers, have recently been extolling the typewriter as almost a necessity for every professional man, comparing the easy, erect attitude at the machine with the position in writing, fingers and arms cramped, body stooping and pressed against the desk or table The injurious effects are particularly noticeable after a hearty meal, or with failing eyesight The typewriter does not strain the eyes, with practice it is possible to use it in the dark The time saved is also a great advantage, as much less time is required to typewrite the same amount of matter The blind were among the first to recognize the utility of the typewriter A light, inexpensive one is now made for them to communicate with each other in the dot language used among them, and the same machine, made heavier, with a pedal attachment, stamps a brass plate, from which any number of copies and books can be printed The physician also requires a light, compact, easily cleaned, durable and comparatively inexpensive typewriter These advantages are only to be secured with a steel type wheel machine The types are all on one small steel spool, which can be taken out and cleaned in a moment They are made interchangeable, with or without medical characters, and in any language Another advantage of this style is that the machine automatically stops printing when the end of the line is reached Many a physician has been enabled to lengthen and utilize his much needed vacation by having his portable typewriter with him, catching up with his correspondence and "getting up those papers" for which he has been collecting notes Where speed is not an object, no skill is required to run the machine, hesitating work and trembling fingers do not affect the printed copy, and writers all find after a little practice that literary work is much facilitated by composing on the typewriter, which shows each sentence in print The *Presse Méd*, recently asserted that "all American physicians now have typewriters in their offices for their personal use" which exaggerated statement we can accept as the customary tribute to our Yankee "appreciation of a good thing when we see it"

Incarceration of the Penis—Dr Theodor Floras, principal medical officer of the Antatolian Railway, Constantinople, reports (*Deutsche Med Woch*, of July 14) a case of incarceration of the penis The patient was a railway employe, about 55 years of age, who, presumably while in a state of intoxication, in the presence of a companion, passed his relaxed penis through the aperture of an iron screw nut, this aperture having a width of only 1 5 centimeters (0 6 in) The matter was treated as a joke, and encouraged by his companion he forced the nut with a twisting movement until it arrived at the attachment of the ligamentum suspensorium urethræ He was subsequently unable to remove the nut, but nevertheless went to work that same day and also the next On the evening of this second day he consulted a surgeon, who drew off his retained urine with a fine catheter, prescribed a diuretic, and directed lead lotion to be applied to the penis It was only next morning that Dr Floras saw him, more than thirty six hours after the application of the nut The man was then in a state of the greatest alarm and uneasiness, his penis hung down like an enormous, tightly filled sausage, and the diffuse swelling was so great that it was difficult to find the nut among the infiltrated tissues Amputation seemed to be unavoidable, but before resorting to it the man was taken to the engineering shop and held by two men in the upright position against a large anvil The penis, with the square nut encircling it, was then held horizontally on the anvil, a slight cut was made in the nut by a sharp chisel, struck by a hammer, and this cut was cautiously deepened until an iron wedge could be driven into it, whereupon the nut broke in two The internal screw threads of the nut had sunk into the tissues of the urethra and had caused ulcerative and necrotic changes, but in a few days all these symptoms disappeared, and the man returned to his work Dr Floras refers to a somewhat similar case recorded by M Ameisen, quoted in the *C für Chirurgie* for 1897, p 1166 —London *Lancet*, July 23

Use of the Galvanocautery—Rice (*N Y Med Jour* for August 20), in a paper on "In What Conditions of the Nose, Pharynx and Larynx the Galvanocautery Should and Should not be Employed," says "Cicatrices in the nose are always to be avoided and should be made as small as possible The galvanocautery puncture needs to be carefully done with an electrode at not more than a red heat The point should be introduced cold and the current turned on perhaps three times while the point is in the same place until sufficient depth of puncture is ob tained The smaller the diameter of the puncture the better This method is resorted to in anterior turbinated swellings only after all obstructions pertaining to the septum have been removed The galvanocautery should never be employed at so great a heat that the opposing surfaces are scorched There are several abnormities of the nasal septum which may be corrected with the electric cautery Small spurs of bone, etc , on the septum may be reduced by a single application of the cautery, sparingly, making a wound not more than one eighth of an inch in diameter Where the nasal partition is deviated as a whole, producing marked obstruction in one nostril, it should not be used The cautery is also of avail as a styptic in some cases of profuse nose bleeding, and prominences of the septum, three quarters of the way back, can be nicely contracted by the cautery The use of the cautery loop or écraseur in removing fibrous and semifibrous growths from the vault of the pharynx, he considers the only conditions of the post-nasal space demanding the galvanocautery, its greatest use being in the middle pharynx It should never be used in the larynx, where few conditions would demand it, except by the experienced

American Medical Operations in Persia —Drs Wishard and Mary J. Smith are at present in charge of the American Hospital and Dispensary at the Persian capital The hospital is a well built stone building, laid out on a scale too extensive for the means and force, but the two completed wings, with the well equipped dispensary just erected, wholly with money given in Teheran, constitute an effective plant Every day is dispensary day, and the crowds of men and women flock into their separate rooms The firman under which the hospital was erected, and the customs and prejudices of the country, prevent the reception of women into the hospital In Tabriz the missionaries feel it necessary to proceed with caution in the establishment of a hospital for women in a residential building, that has already been set apart for that object when the fit time shall have come to occupy it, the popular mind has not yet been educated up to the point of accepting that line of charitable effort In Teheran, however, the women come in swarms to the dispensary Dr Wishard is obliged to act with constant tact and discretion, and under constant limitations caused by the prejudices of the people For example, on one occasion he removed a tumor from the eyelid of a young woman, who, with the aid of two friends, managed to keep most of her face covered with her heavy veil during the greater part of the operation, exposing only the eye, and not minding blood and water and pain, so long as she could maintain the form of hiding her face from us She was not handsome , few of the women are It is only a fruit of the suspiciousness which shows itself in certain western countries in hiding the points of a race horse Woman is an animal to be guarded, suspected, hidden from others and never to be trusted Each man's wife is a prize animal for exhibition only to him This is the case in the cities, while in the villages women are as careless of veils almost as with us Medical missionaries need to be careful as to every assumption of the responsibility for cases The result, whatever it may be, is credited to the doctor Dying patients it is dangerous to receive, as a few deaths in the hospital, maliciously repeated in some false tale by an enemy, never lacking in a Moslem land, might bring a period of long and utter uselessness Yet mercy ever triumphs over prudence Men are often brought wounded or diseased to the hospital gate, and thrown down there One was left in the depth of winter in a ditch at the gate, and was found when nearly dead

Fracture of the Patella —Stimson (*Annals of Surgery* for August) advocates the single free incision as tending to the better protection of the patient in the treatment of this fracture That the operation can be done without once touching the cut tissues with the fingers, he considers an advantage He has frequently done the operation under local anesthesia, as cocain or freezing He makes an incision in the median line, slightly overlapping both fragments, then draws the sides apart and in turn lifts the fragments with a sharp retractor, freeing the surface from clot or fringe While they are thus held up, the joint is thoroughly washed with a hot salt solution The fragments are then drawn snugly together with hooks, the fringe adjusted, and two or three catgut sutures placed in the periosteum along the edge of the fracture, or a single silk or stout catgut suture passed through the tendon and the ligamentum patellæ so that its two strands lie on the front of the bone In the rents in the lateral expansions he sometimes places additional sutures With a continuous silk suture the incision is closed and, without drainage, the dressing applied, the limb being bound upon a posterior splint and the patient kept in bed with the foot elevated for a week, when the silk suture of the incision is removed and a light plaster of paris encasement applied This permits the patient to use crutches in a few days, and after a month the dressing is cut and the patient directed to wear it in the daytime only He finds that the joint can be flexed 90 degrees by the end of the third month, often earlier, the splint usually being entirely discarded before that time

International Red Cross Assistance for the United States —A communication has recently been received by the Secretary of State, from Hon And D White, the ambassador of the United States at Berlin, inviting attention to an appeal made to the people of Germany for funds to relieve the suffering growing out of the war between the United States and Spain The appeal was made by the Central Committee of the German Society of the Red Cross at the instance of the International Committee at Geneva The following is a translation of the appeal

> The war which has arisen between Spain and America is beginning to cause greater misery, especially owing to diseases which have broken out, so that a request for aid has been addressed to us here, through the medium of the International Committee of the Red Cross at Geneva The undersigned Central Committee deems it its duty, in view of the ties which unite the Societies of the Red Cross, and with a grateful recollection of the aid rendered from abroad to the German Volunteer Associations for the care of the wounded in war, to furnish pecuniary assistance to both the American and Spanish Societies of the Red Cross in their efforts to alleviate the sufferings of war In order, however, to prevent too great a diminution of the funds of our Societies of the Red Cross, upon which there is a great demand for their own work and for objects which have greater claims upon them, we apply to such circles in Germany as are willing to contribute to the relief of the wounded and sick in the present war, with the request that they will entrust such contributions to us, and thereby enable us to show the feelings of humanity which are always deeply impressed upon German hearts, even for the sufferings of strangers, and which have been proved by liberal gifts Our undersigned treasurer will receive contributions marked "For the Societies of the Red Cross in America and Spain," and will acknowledge their receipt in the press We also request all the country associations of the Red Cross in Germany to open places for the receipt of contributions

The appeal is signed by the members of the Central Committee of the German Unions of the Red Cross B von dem Kneseback, Vice Upper Master of the Ceremonies and Royal Chamberlain, President, Von Spitz, General of Infantry on the active list, First Vice president, Dr Koch, President of the Directory of the Imperial Bank and Privy Councillor, Second Vice president, Lademann, First State Attorney in the Second Royal District Court of Berlin, First Secretary, Marcinowski, Privy Upper Financial Councillor, Second Secretary, Dr Lieber, Surgeon General on the retired list, General Secretary, Von Burchard, President of the Board of Maritime Commerce, Active Privy Councillor, Treasurer The Central Committee of the German Unions led off the subscription list with a contribution of 10,000 marks, which, so far as the United States is concerned, may all go to the Spanish Red Cross Our own National Society has been generously supported by the people, and the many other relief associations that have been formed have been vying with it and with each other in their efforts on behalf of the sick and wounded Nevertheless it is gratifying to know that through the medium of the International Red Cross material assistance would have come to us, had we required it, from the sympathetic people of other countries

Service on an Army Hospital Train —We have been permitted to copy the report for the week ending August 7, rendered by Major Charles Richards, Surgeon U S Army, as illustrating the arduous service of the Hospital Train of Pullman cars on the railroads between Southern camps and general hospitals in the interior At the beginning of the week, July 31, 1898, the train was en route to Tampa, Fla , from Newport, Ky , in compliance with orders received from the Surgeon General on the previous day Tampa was reached next day, August 1, at 7 30 P M , about three hours late, the delay being due to the movement of troops north from Tampa on the same railroad At this point, Assistant Surgeon Stiles, U S Army, assistant medical officer and acting quartermaster of the train, was taken sick and excused from all duty Owing to the poor facilities at Tampa for watering trains, it was not until after midnight that the train reached Ybor City, where patients were to be loaded Word had, in the meantime, been sent to the Chief Surgeon, Fourth Army Corps, that unless patients had already been sent to the station at Ybor City it would be best to wait until the following morning before taking them on the train However, twenty eight cases were at the station on the arrival of the train, and these were placed upon the cars by 2 o'clock, A M The remaining cases began to arrive a few hours later, but as it rained almost incessantly it was 1 30 P M before all the patients were on the train The total number of patients received was 159 Of these, 121 had the diagnosis typhoid fever and 11 malarial fever The general condition of the patients received was much better than on some of the previous trips, most of the cases of typhoid fever being apparently in the first week of the disease At 1 45 P M the train left for Fort McPherson, Ga , which point was reached the following morning, August 3, at 7 o'clock, and by noon all the sick had been removed from the train, including one member of the Hospital Corps detachment on duty with the train Assistant Surgeon Stiles, being still unfit for duty, was permitted to leave train here and go to Atlanta Many minor repairs were needed, especially to the interior of the cars, and so far as the officer in charge was aware there was no urgency for an immediate return to Tampa, he, therefore, requested the Surgeon General to allow two days at Atlanta for these repairs This was granted, and the train was taken to the Southern Railway shops to enable this to be done By the time the repairs were completed, August 6, orders had been received to take the train to Fernandina, Fla , to receive sick for Fort McPherson, Ga , and to take convalescents and those able to travel to Washington Barracks, D C In accordance with these instructions the train left Atlanta at 4 30 P M , August 6, and proceeded to Fernandina As the train was held at Atlanta for nearly three days undergoing repairs, the number of cases transported during the week was under the average The number of miles traveled was 1700 Although the number of patients carried was less than usual the duties were, perhaps, more arduous for all than those of any previous week in the record of the train Some patients were received after midnight, which necessitated their being visited and prescribed for immediately after their reception The remainder were received during a severe rain storm to which the entire personnel of the train was exposed for hours But few of the patients were able to walk and had to be carried into and out of the train, all of which work devolved upon the train detachment These men performed their trying duties cheerfully and satisfactorily This might not be worthy of note but for the fact, that with a single exception, all of the privates of the detachment have been less than three months in the service, and that in addition to the physical labor of carrying 120 to 130 patients into and out of the cars at the beginning and end of each journey, they have had but little rest, either day or night, while patients are in transit, that their meals are often irregularly served, patients always being looked after first, and that sleep on a railroad car in motion is not as restful as sleep under ordinary conditions

The Human Skeleton —The following alleged boy's composition on bones is doubtless the best thing of its kind that has yet appeared It is from the San Francisco *Impress* "Bones are the framework of the human body If I had no bones in me I should not have so much shape as I have now If I had no bones in me I should not have so much motion as I have now and Grandma would be glad, but I like to have motion Bones give me motion, because they are something hard for motion to cling to If I had no bones, my brains, lungs, head and larger blood vessels would be lying around in me sort of looselike, and might get hurted, but now the bones get hurted, but not much lest it is a hard hit If my bones were burned I should be all brittle, and you could crumble me up because all the animal would be out of me If I was soaked in a kind of acid, I would be limber Teacher showed us some bones that had been soaked I could tie a knot in one I had rather be soaked than burned Some of my bones don't grow snug to my other bones like the branches of a tree do, and I'm glad they don't, for if they did I couldn't play leap frog and other good games I know The reason they don't grow that way is because they have joints Joints is good things to have in bones There are three kinds The ball and the socket joint is like my shoulder joint Teacher showed it to us, only it was the thigh of a cow One end was round and smooth and whitish, that is the ball end The other end is the socket It is saucer like and oils itself Another joint is the hinge joint, like my elbow It swings back and forth, oiling itself, and never creaks like the school room door does The other joint ain't much of a joint It's in the skull and don't have no motion All of my bones put together in their right places make a skeleton If I leave out some or put some in their wrong places it ain't no skeleton Crippled and deformed people don't have no skeletons Some animals have their skeleton on the outside I'm glad I ain't them animals, for my skeleton like it is on the chart wouldn't look well on the outside "

Washington

Health of the District —The report of Health Officer Woodward for the week ended August 20, showed the total number of deaths to have been 112, of which 56 were white and 56 colored The annual death rate for whites was 15 20, for colored, 32 80 The principal causes of death were Kidney diseases, 12, diarrheal diseases, 9, nervous diseases, 11, pulmonary consumption, 14 There were 3 fatal cases of diphtheria and 10 of typhoid fever At the close of the week there were 24 cases of diphtheria and 25 cases of scarlet fever under treatment The annual report shows, for this year, the lowest death rate in the history of the city, it being 19 32 per thousand

Enforces the Medical Practice Act — Health Officer Woodward is to be congratulated on the promptness with which he enforces the Medical Practice Act in force in the District of Columbia He has recently notified Dr A M Curtis that no death certificates bearing his signature will be accepted as valid by the Health Department Dr Curtis is a political appointee, under the Interior Department, which, strange to say, has control and directs the management of the Freedman's Hospital While Dr Curtis, it appears, was appointed after certification of the Civil Service Commission, he has *not* complied with the Act of Congress, requiring registration in the Health Office upon receipt of license from the Medical Supervisors of the District Examining Board The Interior Department claims that their appointee should not be amenable to the District law regulating medical practice and has written to the Commissioners, requesting that the Health Officer be directed to accept the death certificates, signed by Dr Curtis The Health Officer has been unable to find any clause in the Act of Congress regulating the practice of medicine in the District, which exempts Dr Curtis from complying with the requirements of the Act The Health Officer has also decided that Dr Curtis is practicing medicine in violation of the law, and has directed the Coroner to review all cases of death reported on the certificate of Dr Curtis The local profession cordially endorse the action of Dr Woodward

Woman's Dispensary —The annual report of the Woman's Dispensary shows the total number treated to have been 2852, number of new cases during the year, 1101, number of surgical operations, 48, number of prescriptions compounded, 2841

WASHINGTON ASYLUM HOSPITAL — The report of Dr D Percy Hickling, the visiting physician to the Washington Asylum Hospital, has been submitted to the District Commissioners It shows the total number of patients treated during the year to have been 941, of whom 488 were white and 453 colored The daily average attendance of the hospital was 85, number of prescriptions compounded, 28,900, total number treated in the Alms and Workhouse, 4062, insane cases examined, 57 He recommends an appropriation of $7,000 for building a new maternity ward, and $15,000 for building and furnishing a receiving ward for infectious diseases He further recommends a nursery and an ambulance for emergency service, and a fumigation plant for patients' clothing, etc He asks for an appropriation to furnish the nurses' home, and a salary for a trained nurse to have charge of the nursing in the hospital

HOSPITAL FOR INCURABLES —The report of Mrs Helen D McLanahan, the acting President, shows that the total number treated during the year was 55, number of deaths, 11 On June 30, 53 patients were in the house, of whom 12 were pay patients The total expenditures for the care of the hospital were $12,731 65 She recommends a Congressional appropriation of $5 000 for the current year

COLUMBIAN UNIVERSITY HOSPITAL —The Columbian University Hospital, adjoining the Medical Department, is about to be occupied The hospital is equipped in the most modern style, with large, well ventilated wards for males and females and a number of private rooms It has an operating room of modern design and spacious The building is lighted by electricity and is provided with an elevator and cold storage room The physicians connected with the Medical Department of the University constitute the attending and consulting staff

Dr C G MORRIS has been commissioned an acting assistant-surgeon, U S A, and has been ordered to Chickamauga Park Hospital Ga

Dr J M HELLER, acting assistant surgeon, U S A has been relieved from duty at Fort Washington, Md, and ordered to Camp Wikoff, Montauk Point

THE PUBLIC SERVICE

Movements of Army Medical Officers —To duty at Camp ikoff, Montauk Point N Y Lieut Col Nicholas Senn U S Vols, Major J L Powell Surgeon U S A Major Ira C Brown, brigade surgeon, Major Simon P Cramer, brigade surgeon, Major Samuel W Kelly brigade surgeon, and Acting Asst Surgeon John J Cannan from Williamsport, Pa To duty at Camp Meade near Middletown, Pa Major David C Peyton, brigade surgeon and the following acting assistant-surgeons W L Stevens from Orange, Va, Edward Lyon, Jr, from Washington, D C, D N Grealish and Frederick H Mills from Buffalo, N Y, H M Miley from Chambersburg Pa H M Cohen from Baltimore, Md, and E W Karrmann from North Woodbury, Conn To duty with troops at Fernandina Fla Capt W F Lewis Asst Surgeon U S A his orders to accompany the 5th U S Infantry to Santiago Cuba, having been revoked To duty with troops at Santiago Cuba Major John G Davis from duty with the 7th U S Vol Infantry at Jefferson Bks Mo, and Major John J Archinard from duty with the 2d Louisiana Vol Infantry at Jacksonville, Fla To duty with troops at Ponce Porto Rico, via New York Acting assistant-surgeons Azel Ames from Washington D C Clarence M Spalding from Rochester, N Y, and Halsey L Wood from New York City To duty with troops at Chickamauga Park Ga Brigade surgeons U S Vols Charles Adams, Oscar Le Seure, John L Macumber, Bial T Bradbury and Henry H Lee, with the following acting assistant surgeons Milton D Norris from Baltimore, Md, Wm G Young from Grand Rapids, Mich, Frank A Roberts from Camden N J Wm P Earle from Herkimer N Y, Josiah W Richards from Slatington, Pa, James A Keown from Lynn, Mass, Charles A Cattermole from Lansing, Mich Albert N Jacob from Philadelphia Pa, Dwight B Taylor from Norwalk, Ohio Chas H Stoddard from Milwaukee Wis, Andrew Godfrey from Ambler, Pa, Chauncey T Scudder and Chas I Woolford from Baltimore Md To duty with troops at Huntsville Ala Major Chas M Gandy brigade surgeon with the following acting assistant-surgeons Geo F Jennermann from Washington D C Charles C Jolliffe from New York City, Gustavus C Thieme from Baltimore, Md, Chas H Andrews from Buffalo N Y, and J Frederick Haller from Providence N Y To duty at Camp Alger Fall's Church, Va Chief Surgeon Francis R Perceval from Washington D C To the general hospital Fort Myer Va Major John E Woodbridge, brigade surgeon, and Acting Asst Surgeon D H Lamb from Owosso Mich To duty with troops at Chickamauga Park, Ga the following acting assistant-surgeons Duncan S Worth from St Louis Mo Herbert M Huston from Ruthven, Iowa, John B Alcorn from Gallipolis Ohio, T H Lander from Canton Ohio Harry A Barnhardt from Philadelphia Pa Wm E Stemsen from Kansas City Kan E D Meeker from Trenton Mo and A G Donaho Jr from Hartsville Tenn To report to the commanding General at Ponce Porto Rico, for duty with troops proceeding via Fort Monroe Va Acting Asst Surgeons William J Hughes from Baltimore, Md John N Goltra from Buffalo N Y Michael E Hughes from Adams, Mass and Compton Wilson from Norfolk, Va Via Charleston, S C Acting Asst Surgeons Frank I Disbrow from New York N Y, *James Reagles* from Schenectady N Y, Charles H Farr and Edward A Southall from Buffalo N Y and Harry Street from Baltimore Md To the 4th Army Corps at Huntsville Ala Lieut Col R M O Reilly, chief surgeon of volunteers From the 4th Army Corps to Ft Ethan Allen Vt Capt H D Snyder Asst Surgeon U S A To report to the commanding General, Camp Wikoff Montauk Point, L I for duty with troops Major John P Dodge Surgeon U S Vols Major Leonard B Almy chief surgeon of volunteers from the 2d Army Corps Capt F A Winters Asst Surgeon U S A and acting assis*tant Surgeons Joseph M Heller from Ft* Washington, Md and William F Skinner from St Thomas Pa To the Dept of Santiago reporting to the commanding General Lieut Col Valery Havard, chief surgeon of volunteers, as chief surgeon of the Dept, from duty with the 5th Army Corps Capt W F Lewis, Asst Surgeon U S A to accompany the 5th U S Infantry from the United States, and the following acting assistant surgeons proceeding via Tampa, Fla W L Coleman from Houston, Texas, John F Cronin from Savannah Ga L De Poorter from New Orleans, La, John B Sewell from Baldwin La W H Aylesworth from *Fairfield, Iowa* E J *Kenworthy from Tryon* N C Louis J Genella from New Orleans, La G W Luster from Utica Miss, J M Lindsley from Nashville, Tenn E F McClendon from Smithville Texas W E Moody from Hermanville Miss, W H Reynolds from Packsville S C O W Stone from Bay St Louis Miss Batt Smith from Wharton Texas and A L Izlar from Ocala, Fla From the 5th Army Corps to Washington, D C for instructions Lieut Col Benjamin F Pope chief surgeon of volunteers To the U S hospital ship *Missouri* Acting Asst Surgeon John E Brackett from Washington D C To the U S general hospital *at Montauk Point, L I Acting Asst Surgeons E Nunez from Philadel*phia Pa and Frank Donaldson from Washington D C From the U S general hospital Key West Fla to Key West Bks Acting Asst Surgeon Geo R Plummer To the U S General Hospital, Ft McPherson, Ga Capt W E Purviance Asst Surgeon U S A from Ft Morgan Ala, and Acting Asst Surgeon John H Grant from Buffalo N Y To the U S general hospital Ft Myer, Va Acting Asst Surgeons Geo W Pattison from Buffalo, N Y, and Geo M Bradfield from Philadelphia Pa

Promoted —Major Victor C Vaughan from surgeon 33d Michigan Infantry *to chief surgeon of division U S Volunteers*

Resigned —Major Chas M Robertson chief surgeon of volunteers Major Henry G Fish surgeon 3d Regiment volunteer cavalry Major John W Harriman 50th Iowa Vol Infantry and Lieut James A Toole Asst Surgeon, 3d Regiment volunteer infantry

Died —Major Lawrence Smith Surgeon U S Vols on the hospital ship *Relief*, while en route from Ponce, Porto Rico, to New York City

THE SURGICAL TREATMENT OF UTERINE MYOMATA

Presented to the Section on Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY HENRY O MARCY, MD , LL D
BOSTON MASS

In the rapid progress of events, the timid steps earlier taken in a most careful way, in the devising of better surgical methods, are now naturally considered of little importance However, historical studies are of interest and value of interest, in that they show the thoughtful, reflective judgment of men who considered the gravity of the problems upon which a life is ever more or less dependent, of value, since they point out the way, open ever, but only, to the real student who seeks the ideal, regardless of self-interest, and especially in the fruitage of averted suffering and the saving of life beyond the hope of previous generations

Based upon ample data, collected with painstaking care, a generation ago, military surgery was rewritten and stands today as the enduring monument of my early master, the late George A Otis, Surgeon U S Army The slowly developing interest in the surgical diseases of women was held in abeyance, as a seeming side issue of little importance at the close of our late war, and the few more courageous men who presumed to devote special study to this branch of surgery were looked down upon as men of doubtful importance, by the body politic, and unworthy the highest consideration of the public The late Dr Gilman Kimball of Lowell[1] appears to have been the first surgeon in the world who deliberately determined to attempt the removal of a large uterine myoma by abdominal section, which was followed by the recovery of the patient, and who planned step by step the procedures which he regarded essential to its accomplishment, and yet such was the criticism of his well meaning contemporaries that I was personally advised to avoid his acquaintance as detrimental to my professional repute

Dr W Burnham of Lowell, in 1853, only a little time previous to Dr Kimball's operation, removed a large fibroid tumor, followed by recovery of his patient However, he began his operation in the belief that it was an ovarian cystoma Dr Burnham passed a strong ligature through the neck of the uterus and tied it on each side Then to make doubly sure against hemorrhage, a ligature was placed round the whole neck The ovaries were removed The cervix was dropped and the ligatures were brought out at the lower angle of the wound They came away during the fifth week Dr Kimball operated very much in the same manner, but, eight months later, he reported that the ligatures were still attached Such was the heroic courage of Dr Burnham, guided by the conviction that relief should be rendered this unfortunate class of sufferers, that he continued to operate from time to time until 1876, in all fifteen operations with only three recoveries Heath and Charles Clay of Manchester, England, were doubtless the first who removed uterine fibroids by laparotomy, in 1843 and 1844, but both patients died

The first Boston surgeon and the third in America to perform suprapubic hysterectomy was Dr H R Storer, Sept 23, 1865[2] The criticism of his unwonted daring was almost universal and made so condemnatory that not one of his little circle of assistants was permitted to escape in sharing of it The short cycle of a generation which has supervened since that period has worked most remarkable changes In no other department of surgery have such striking victories been won as those now universally accredited to gynesic surgery Every American surgeon points with pride to our McDowell, who, although described as a frontiersman of the West, profited by his careful Edinburgh training, and in the freedom of his new surroundings dared to think for himself This opened the way for abdominal surgery with its many present brilliant subdivisions, in which every abdominal organ has been a sharer It would seem almost invidious to name any of the long series of most distinguished men who have labored to bring about, perhaps the greatest triumph of modern aseptic surgery, the present comparatively safe surgical removal of uterine myomata Indeed, it is not necessary, since to you the names of these leaders are not alone household words, but their personal influence has been felt and still governs a large share of those whom I have the honor of addressing

Schroeder, in 1874, advocated the treatment of the pedicle of fibroid tumors by including it in the lower angle of the abdominal wound after the method of Koeberlé of Strasburg, or returning it into the cavity of the abdomen, after ligating or cauterizing it much in the same way as advised for the treatment of ovarian tumors In December 1879, he had operated eighteen times with eleven recoveries, and he then advocated the amputation of the uterus at the level of the os internum The ovarian arteries were ligated on each side, and the cervix was tied in two portions, each including an uterine artery The uterine stump was cut V-shaped, the muscular walls were closed with coarser, the peritoneal covering with finer, interrupted silk sutures

In 1880, assisted by my distinguished teacher, Dr Gilman Kimball of Lowell, I removed the uterus for the first time for a large multiple myoma, when I adopted a modification of Schroeder's method, embodying all that is at present considered essential

[2] American Journal of Medical Science June 18[illegible]

Commencing on one side, I sutured the broad ligament with a double continuous tendon suture, extended so as to include the cervix The broad ligaments were divided, the peritoneum reflected from either side, the stump cut down conically, and this was covered over by an intrafolding of the peritoneum with a continuous sero serous animal suture The suture thus taken intrafolded the peritoneum evenly, while it was itself buried beneath it, leaving no line of infraction of the pelvic peritoneum Thus the stump, while dropped within the abdomen, was itself *extra-peritoneal* This method seemed to me so important an improvement upon that of Schroder that I reported it in a paper[3] read at the International Medical Congress, held in London, in 1881 I incorporated it in further detail in my address[4] upon "Fibroid Tumors of the Uterus," as President of the Section of Obstetrics and Diseases of Women, of the AMERICAN MEDICAL ASSOCIATION in 1882 In 1887,[5] I reported still further my experience with this method and emphasized its value I also pointed out the importance of dealing with the larger number of uterine myoma which develop in such a way as to have really no pedicle My last special contribution upon this subject was a paper entitled, "The Surgical Treatment of Non-Pedunculated Tumors," read at the AMERICAN MEDICAL ASSOCIATION in May, 1890 Up to that period, in common with nearly every abdominal surgeon, I had considered hemorrhage as the greatest of all dangers, and in order to lessen this, I advocated and used the so-called rubber dam, a thin sheet of rubber with a central reinforced opening which was stretched over the tumor and crowded down as far as possible to its base, around which was placed a constricting rubber ligature The suggestion of its use occurred to me from noting the admirable service rendered the dentist by the constricting rubber placed around the root of a carious tooth It served the double purpose of controlling hemorrhage and keeping the abdominal cavity entirely free from surgical contact This was applicable, however, only to movable tumors with a more or less distinct pedicle

Dr L E Stimson certainly made one of the most valuable contributions upon this subject by ligating the ovaries and uterine arteries preliminary to hysterectomy He did this at first in order to perform a complete hysterectomy, but the teaching that hemorrhage might be controlled by the ligation of these arteries bore immediate fruitage in lessening the almost universal fear by the surgeon of the danger of hemorrhage One has only to observe the enormous dilatation of the venous plexus, commonly accompanying large uterine myoma, to understand the reason of the fear and the real danger occurring from hemorrhage It was on this account that I included the entire broad ligaments on either side by my method of double continuous en masse suturing

In 1892, Dr B F Baer made his valuable contribution to this subject, in which he modified the operation of Stimson by ligating the arteries independently, while he left the cervical structures as a pedicle, quite in accordance with the method which I advocated The adoption of new methods with the improvement of aseptic procedures has firmly established hysterectomy as a well-advised and comparatively safe operation for the removal of large uterine myoma

Dr Joseph Eastman of Indianapolis has done valuable work in the removal of the uterus, including the cervix for fibroid tumors He met with exceptional success in so doing, and has devised instruments of special type, which are valuable accessories for this purpose

In an exceedingly interesting article, Dr Charles P Noble of Philadelphia, upon "The Development and the Present Status of Hysterectomy for Fibroid Myomata," gives Dr Eastman the credit of first covering the pedicle with a double flap of peritoneum, which he states was similar to an operation of Dr Emmett, performed in 1884 It will be noted, however, that I had deliberately effected this for the purpose of making the stump extraperitoneal in 1880, and published the same in 1881 and 1882

The method of intraperitoneal fixation of the pedicle was of very slow adoption owing to the excessive fear of surgeons lest secondary hemorrhage might ensue The fixation of the pedicle in the abdominal wall placed it where it could be kept under observation, but the mortality was so great that various ingenious modifications of this method were devised One of the most interesting of these was by Dr H R Storer of Boston, who sewed the pedicle, including also the ovarian tumors, into the lower angle of the abdominal wound for the purpose of shutting off the peritoneal cavity This he called "pocketing the pedicle"[6] This operation was revived by Dr H A Kelley of Baltimore, in 1888, with the addition of the use of a temporary elastic ligature

The first operation for the removal of the uterus, including the cervix (total extirpation), for fibromata, is accredited to Dr Mary Dixon Jones of Brooklyn, N Y, who operated Feb 16, 1888, whereas Dr Eastman's first total extirpation bears date of August, 1889

Dr H A Kelley furnishes a valuable contribution with the title "Hysterectomy by Continuous Incision from Left to Right, or from Right to Left," November, 1895 It shortens the time of the operation by commencing at one side, securing the vessels, dividing the cervix, and under tension made upon the tumor, the uterine artery of the opposite side is easily exposed and seized with forceps The division is continued until the ovarian artery is the last vessel secured The vessels are ligated, the stump covered over by a continuous over-and over-suture of catgut Emphasis is made upon the importance of commencing the incision upon the side where the ovarian vessels and tube are most accessible

There is an undoubted gain by this method in the saving of time, and the certitude of work accomplished, and very generally this is greatly facilitated by placing the patient in the Trendelenburg position Although this paper is not intended to be an historical treatise upon the subject, and as a consequent, many of the most worthy workers in this field have not been mentioned, it seemed to me necessary to follow the line of thought the development of which has brought the present operation of hysterectomy to such greatly reduced rate of mortality, a danger not so very much greater than that attending the removal of an ovarian cystoma It is very probable that further modifications of this operation will be adopted in the hope of giving still greater safety and satisfactory results The greatest reason, however, why recent statistics show such marvelous improvement lies in the fact, just as pertains to the history of ovarian cystoma, of the greater confidence of the surgeon, who, as a consequent, advises early operation for comparatively small tumors, which, only a brief period ago, would have been let alone without discussion of operative measures

[5] Histology and Surgical Treatment of Uterine Myoma President's address, Sect of Gynecology, Ninth International Mod Congres, 1887 Vol xi, pp 835-841

[6] Journal of Gynecological Society Vol i, p 150 Sept 23 1867

The ovarian cystoma which has obtained any very considerable size is likely to have become adherent, and these complications render ovariotomy much more serious and dangerous than the treatment of the pedicle per se On the contrary, the enlarging myomatous uterus is not likely to form adhesions until at a late period of its development, and its removal is attended with danger chiefly because of the basic structures which must be divided A supravaginal hysterectomy, therefore, must necessarily involve much greater difficulty than the separation of the ovarian pedicle

In a very large percentage of cases taken under advisement for operation the pelvic basin is filled with more or less of these growths, and the functions of the pelvic organs are so interfered with as to demand relief Here adhesions are common, the relationship of the structures disarranged, the intestines and bladder not rarely involved, and the ureters are in dangerous proximity to the growth to be removed Such cases will ever tax the most resourceful of operators, and the greater the experience the more will the surgeon consider the responsibility of his duty Oftentimes multiple masses are to be enucleated until at last the uterine arteries are seized upon well down in the cervical region After the tumor has been removed, the vessels ligated, not seldom a very important part of the operation consists in the reconstruction of the pelvic peritoneum I exercise more and more care in this direction with each succeeding year

Hemorrhage, the former greatest danger of the surgeon, is now practically eliminated from the problem, and septic infection, the peritonitis of the earlier day, is almost equally rare In my last hundred hysterectomies I have not had a single death from hemorrhage or from septic infection Almost the only cause of death has arisen from intestinal obstruction, induced by infractions upon the peritoneal surfaces, and it is in this I am exercising the greatest care I recognize the value and importance of time to the patient in prolonged operations, but the rapid surgeon never hurries "Well done is quick enough done," was the maxim of the elder Crosby The surgeon should ever be assured of the integrity of the intestinal canal, and as far as possible avoid conditions which may induce obstruction Adherent omentum not seldom leaves rents through which a loop of small intestine may easily slip All adhesions of the peritoneum should be closed This is easily effected by suturing in the same manner as that employed in covering the cervix with the intrafolded peritoneum A fine tendon is selected and by a loop stitch fastened in one end of the adhesion The full-curved small Hagedorn needle is made to penetrate through the healthy peritoneum a few lines from the edge of the rent and parallel to its long axis Each stitch is inserted directly opposite the emergence of the preceding one, in the same way on the opposite side of the peritoneal rent, and thus from side to side the suturing is continued until the rent is closed When drawn upon, this sero serous suture evenly intrafolds the peritoneum, while it is itself completely buried An exposed ureter may be easily covered in this way, and when the pelvic peritoneum is much disorganized I have not seldom sutured the peritoneum of the entire pelvic basin in even juxtaposition quite to the pelvic brim I emphasize this method of closing the peritoneum, especially of the pelvis, since I am sure by it little harm can come from the future disarrangement of the organs, that it does not interfere with the rectum or bladder, and that it does materially lessen the really very great danger of adhesive processes so liable to induce obstruction of the intestines and subsequent functional discomfort, while it is now recognized as by far the most common cause of acute intestinal obstruction

The variety of methods under discussion at the present time is limited chiefly to suprapubic hysterectomy as above described, to the removal of the uterus, including the cervix, to the saving of as much of the uterine tissue as possible when the myomata are small and not too numerous, and finally to the advantage of leaving the adnexa (the ovaries and tubes) when the conditions will permit Each of these different methods have certain possible advantages As I believe, for reasons already stated, the larger number of hysterectomies for uterine myoma should have a certain portion of the cervical tissue left Generally the operation is less difficult and more rapid The remaining structures furnish a means of support to both bladder and rectum, the vagina is uninjured and the relations of the pelvic organs are maintained in easy mobility, conditions having a value in marital life of great importance The objections to this are the possibilities of infection of the wound through the cervical canal and lack of drainage, where conditions of the pelvic basin may render drainage an important factor To my mind these criticisms are, at the most, of minor importance, since the cervical canal can easily be disinfected or the entire mucosa removed Should drainage seem desirable, and each year this is considered of less importance, it can easily be provided for by an opening through the posterior fornix

There are conditions in which it may be of decided advantage to remove the entire uterus Doyen of France has modified the technic of complete hysterectomy, which, briefly, consists in making forcible tension upon the uterus and myoma by drawing it forward over the pubis through the abdominal opening and then incising the vagina posteriorly This permits pulling the cervix upward into the abdomen, which makes tension upon the broad ligaments First one is divided and then the attachments of the uterus to the bladder are separated, and lastly the other broad ligament is divided These are seized and held by assistants during the operation and until the arteries can be independently secured It will be noted that by such a measure the operative field is brought clearly into vision greater safety as well as celerity attained since the relationship of the ureters intestines and bladder can be determined with much greater certitude After hysterectomy has been thus performed complete peritoneal closure of the pelvic basin may be made if considered advantageous This leaves a wound open only from below, which may be lightly packed with iodoform gauze Dr W P Allen of Cleveland has contributed a valuable article upon complete hysterectomy, in which he advocates two modifications of Doyen's method, both preliminary to the abdominal section The cervix is curetted and packed with antiseptic gauze, the vagina is carefully disinfected, the cervix seized with a strong pair of vulsellum forceps and drawn downward With the cautery the vaginal tissue about the cervix is dissected The advantages claimed are "1 Asepsis is secured with more certainty than by any other method 2 The division of the vaginal vault by the cautery is in most cases performed quickly and without hemorrhage If the cervix be very short or difficult to reach, as is sometimes the case when the fibroid is developed in the lower part of the uterus, its separation by the cautery may be unusually difficult It can, however, usually be accomplished" "The abdominal cavity is not opened from below A long pair of slender, curved forceps is now used to seize the tissue just behind the cervix at the point at which it is divided by the cautery The object of this pair of forceps is that when the abdomen is opened, the forceps may be pushed upward into Douglas' cul-de sac, and marking absolutely the vault of the vagina, enable the surgeon with certainty and rapidity to open downward into the vagina With long vulsellum forceps the cervix is firmly seized and drawn upward and backward into the abdominal cavity" Dr Allen thinks the operation of Dr Doyen as thus modified greatly shortens the time consumed in the removal of the uterus, while the intestines, ureters and bladder are much more easily avoided, and he recommends it for favorable consideration

By general consensus of opinion, little by little, the cautery has been relegated to history, and at present, when asepsis makes a certitude of primary union, the use of any means which leaves of necessity necrosed structures should, if possible, be avoided Dr Eastman's hysterectomy staff easily fulfills every purpose sought to be attained by Dr Allen with his fixation forceps to mark the point of posterior vaginal section

It not seldom happens that uterine myoma are found which may be advantageously removed, leaving the uterus more or less damaged or deformed Dr A Martin of Berlin was among the first and most earnest advocates of myomectomy More than ten years ago this seemed to me the ideal method, and I examined all the cabinet specimens preserved in the Boston and New York museums for the purpose of determining its possibility I also made a large series of sections of the smaller growths in order to establish the relation between the tumor and its parenchyma, the so called capsule

The accompanying photographs will show that this is developed from the deformed surrounding uterine muscular structure, and that the tumor itself usually receives its nutrition from it rather than by vessels directly penetrating its substance In one instance, however, I succeeded in injecting the vessels of the tumor through the uterine arteries Unfortunately, it happens that in the great majority of instances the myomata develop from a considerable number of independent centers, whatever may have been their cause and as a consequent the uterus can not be preserved intact, and the invading growths removed In exceptional cases this may and should be done In common with other operators I have not infrequently removed a considerable number of these growths, and do not recall a single case where convalescence did not easily follow The constricting rubber-dam is often of much service in this operation, since it may make the operation bloodless It is my habit to occlude the cavity with continuous tendon sutures and introflect the divided peritoneal surface over it The pendulum of opinion upon this operation swings to both extremes Dr Noble above quoted, closes his paper as follows "Myomectomy is the ideal operation for fibroid tumors The next advance in the treatment of fibroid tumors will be the acceptance of early operation, with the definite purpose of substituting myomectomy for hysterectomy in women of child bearing age in cases having a small number of fibroid nodules" At the last meeting of the British Gynecological Society, Dr W Alexander of Liverpool urged the enucleation of multiple uterine myoma as a favorite alternative operation to hysterectomy, and that it being a non-mutilative operation it presented a marked advantage over total removal of the uterus The society did not accept his views, but rather Mr Bland-Sutton's terse summary, who claimed "that in most cases such tumors were developed after the child-bearing period, when the uterus was a non-important organ He felt sure that a woman was much better off with ovaries and no uterus than with uterus and no ovaries" Dr J F Baldwin of Columbus, Ohio, advocates in abdominal hysterectomy the fixation of the round ligament between the cervical flaps, which holds it *in situ* by buried animal sutures He claims the advantage to be in the fixation of the parts and preventing prolapse of cervical stump in the vagina

There can be no doubt but that the improved operations for the comparatively safe removal of large uterine myomata had not alone its inception, but its development to its present successful status in very much the larger degree with American surgeons, the credit of which should be given to American surgery Within the last half decade, under the leadership of Doyen, Segmund, Richelot and others, vaginal hysterectomy has been successfully developed, especially for the removal of small uterine growths, quite beyond anything attemped in this country in this operation Vaginal hysterectomy for cancer is more especially a German operation in its origin Intrauterine myoma for a long period have been successfully removed per vagina by morcellement, even when of very considerable size At an earlier period I removed a number such growths by this method, one weighing four pounds, where I am convinced I should now perform abdominal hysterectomy, and this because of our greater confidence in an improved technic for abdominal hysterectomy The French school have advised special methods for operating upon the pelvic structures through the vagina, here, usually performed by the abdominal route Their brilliant successes were at once accepted with approval by some surgeons in America and have at present their advocates It is very probable, however, that this vaginal operation has been popular in France in a large degree owing to their comparative unfamiliarity with abdominal hysterectomy, which they are pleased to style "the American operation"

Blind surgery is bad surgery, and on this account vaginal operations upon the pelvis must ever be held to a certain degree in criticism If, for instance, a small uterine myoma is to be removed, the choice of the vaginal route, under certain conditions, might advantageously be made In a large degree this too is an American operation, first advocated and performed by our lamented fellow-countryman, Dr Robert Battey of Georgia In 1879 I first removed a fibroid tumor through Douglas' cul de sac (a myomectomy), saving the uterus However, in much the larger class of cases, where it is judged wise to remove uterine myomata sufficiently small to accomplish the work through the vagina it is undoubtedly better to operate by the abdominal route, since this is the class of cases most suitable for myomectomy

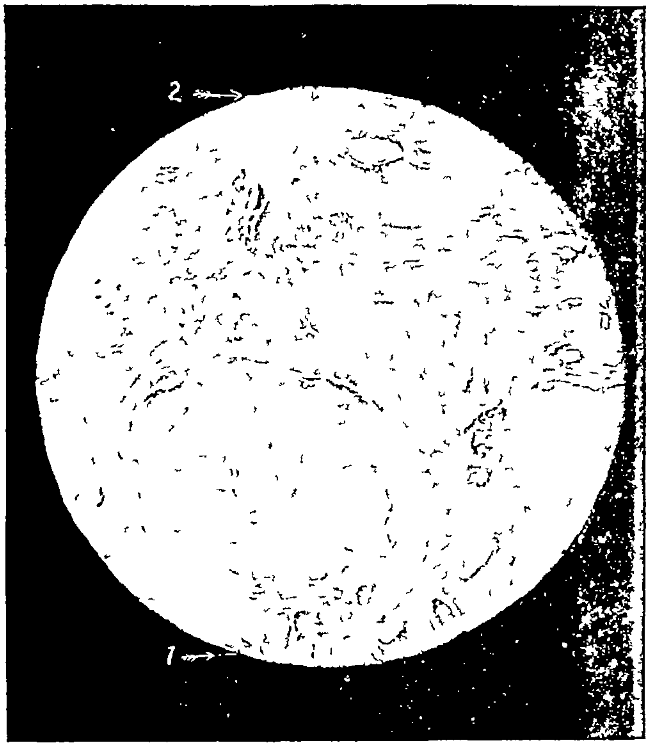

Fig 1 —1 small uterine myoma Singular resemblance to a fetal head 2 uterine cavity Specimen injected vessels much enlarged

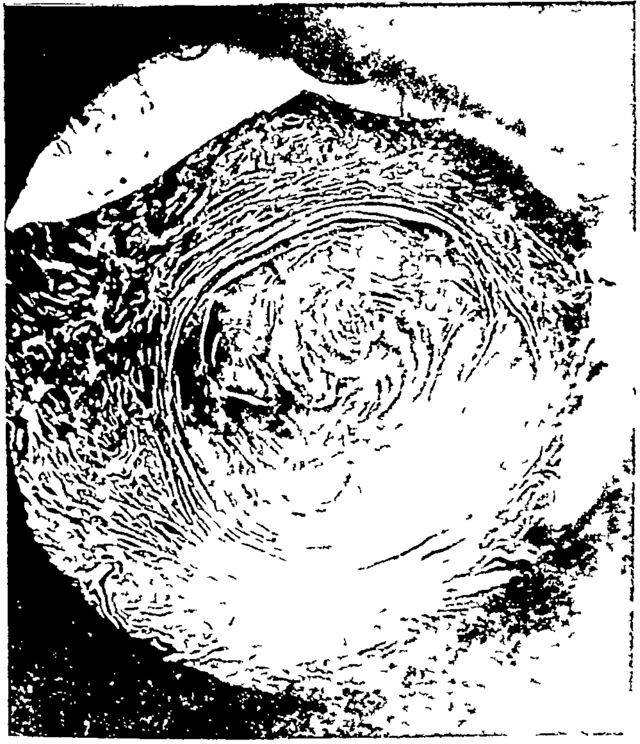

Fig 2.—Uterine myoma with multiple centers Capsule formation well pronounced

Little further need be said in reference to the technic of the operation It must be conducted as far as possible under strict aseptic conditions An uninfected abdominal cavity, left in good condition, should be closed without drainage The abdominal

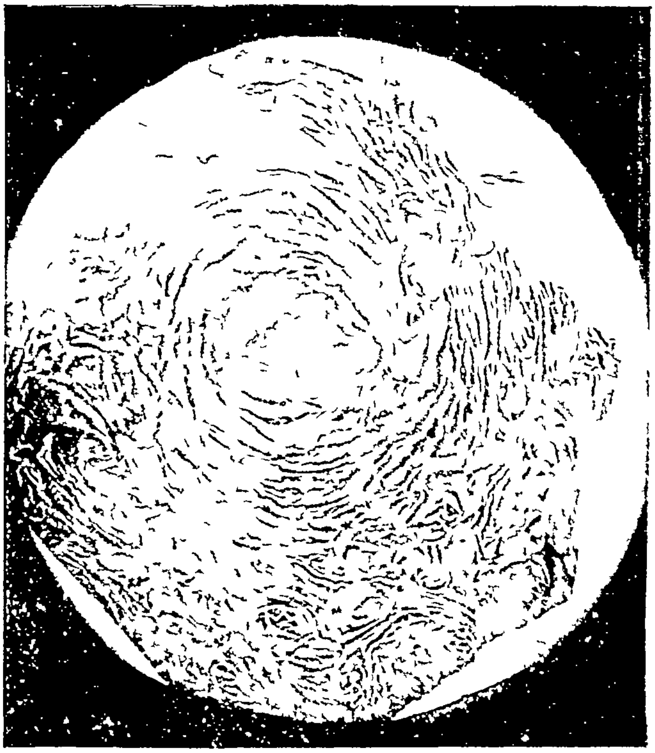

Fig 3 —Section from just over a small myoma The encircling blood vessels and capsular formation well shown

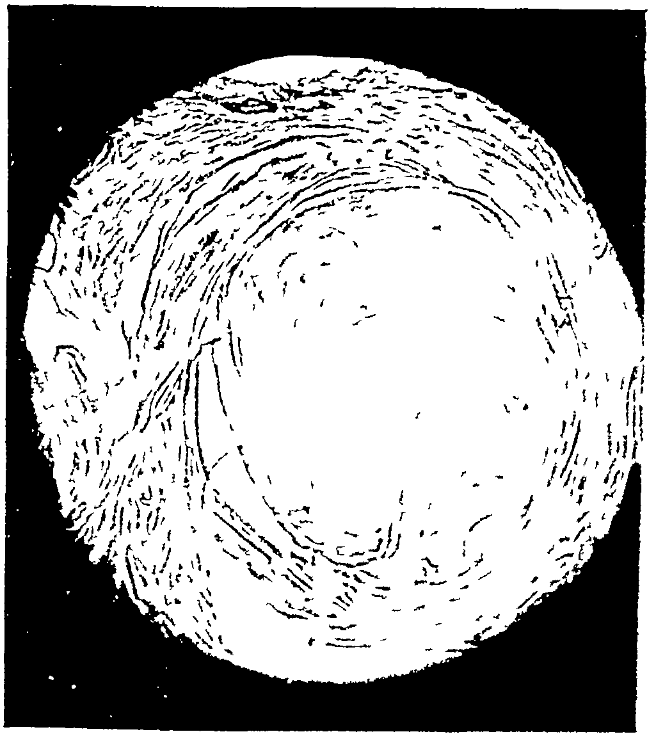

Fig 4 —Large [illegible] greatly enlarged

wall is reconstructed by independent lines of continuous buried tendon sutures I consider the peritoneum and thick fascia can be much more satisfactorily reunited by the use of the double continuous tendon suture A subcuticular, fine tendon suture is much to be preferred for holding in coaptation the edges of the skin The final dressing consists in the application of contractile collodion, holding in solution iodoform, reinforced by a few fibers of absorbent cotton Unless the tumor is of exceptional size the patient is usually more comfortable without the application of an abdominal bandage The advan-

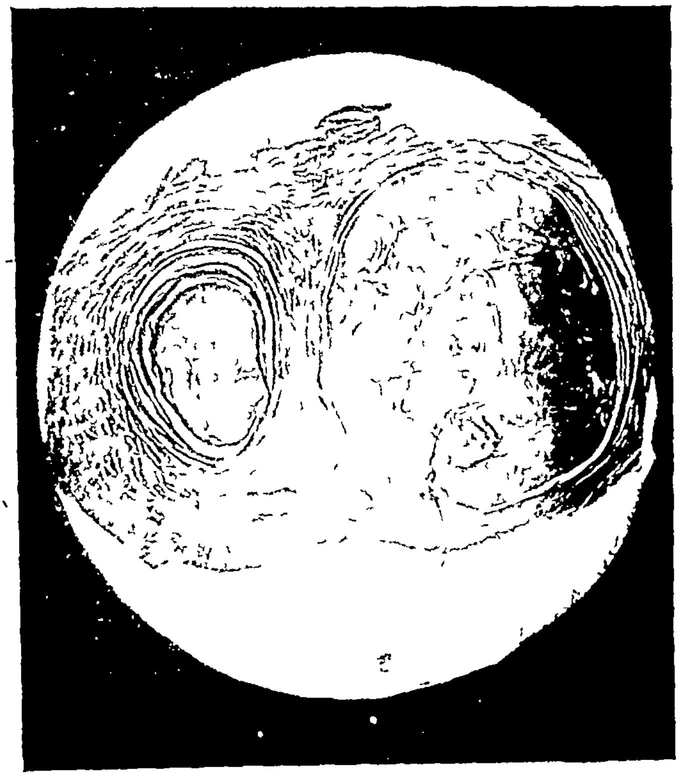

Fig 5 —Double uterine myoma Capsules well developed Tumors slightly vascular

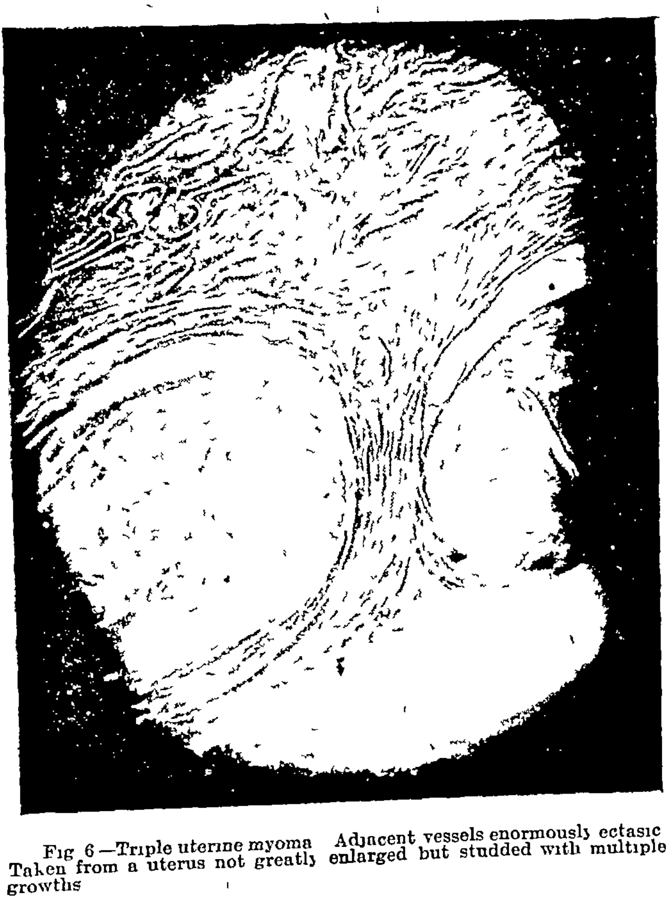

Fig 6 —Triple uterine myoma Adjacent vessels enormously ectasic Taken from a uterus not greatly enlarged but studded with multiple growths

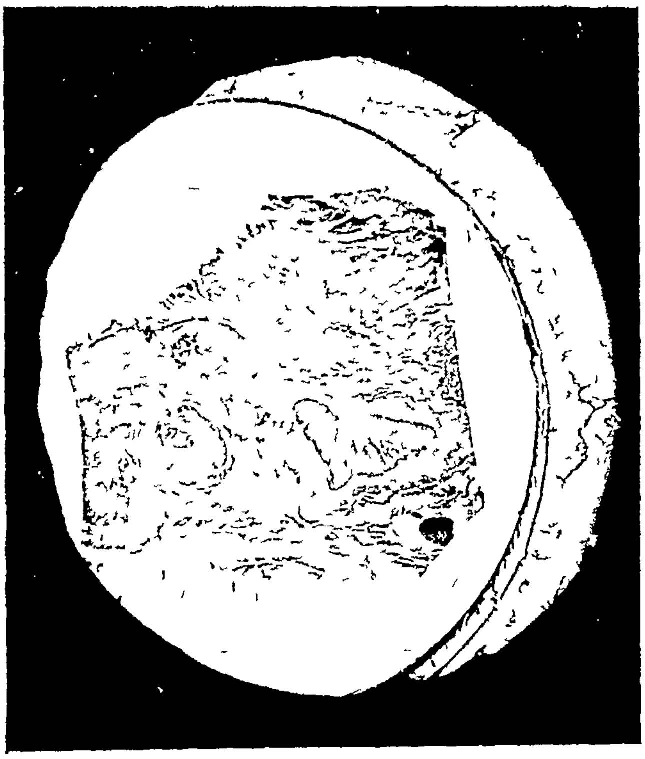

Fig 7 —Calcified tumor Infiltration by lime salts Uterine myoma showing process of calcification The dark spots mark the lime deposit

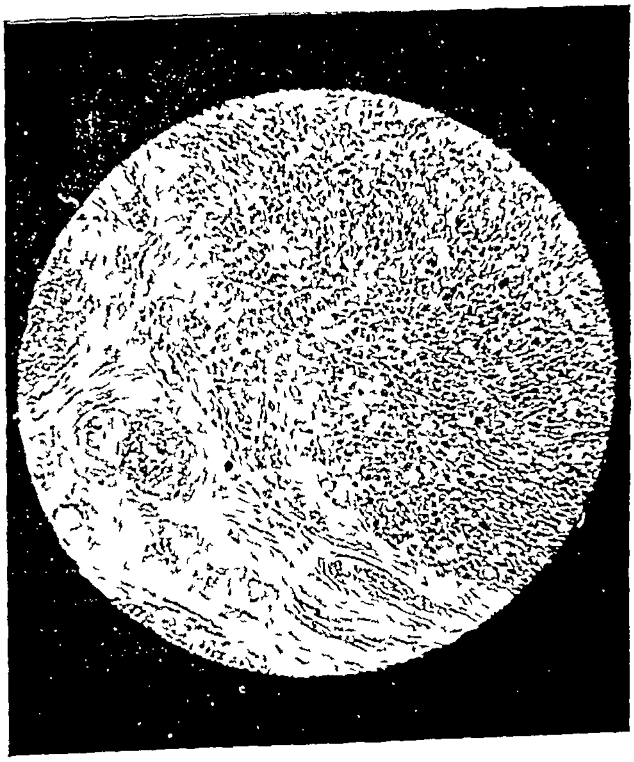

Fig 8 —Section shows the cell disposition In the larger portion the cells are cut transversely

tage derived from suturing the abdominal wound in layers is so apparent that I find its adoption is becoming more and more common I have thus sutured since my first advocacy of buried animal sutures quite twenty-five years ago, and for fifteen years with no other dressing than the collodion seal Subsequent hernia does not occur, and in over eight hundred laparotomies I recall but one case of subsequent hernia, and this in a case where the abdominal wall had become excessively thin from a large fibroid tumor

A final question for consideration is the ever recurrent one When shall we operate? As in ovarian cystoma, so here the pendulum of opinion constantly varies Without doubt the larger number of abdominal surgeons are operating on cases today, which they would have judged ill advised four years ago In young women, small growths which cause pain, excessive menstruation and interfere with the functions of the pelvic organs should be no longer subject to unsatisfactory medication, since operation in these cases gives the lowest rate of mortality, and not seldom by a myomectomy results in complete restoration of unmutilated organs with restored functions There is a general consensus of opinion that the patient will profit less by the cessation of the menopause than was earlier believed

Many of the more dangerous growths develop comparatively late in life, a considerable percentage of which go on to most extraordinary development regardless of menstruation When the patient is still within the cycle of menstrual life and the ovaries comparatively healthy, it is probably wiser not to remove them It is my own belief that in the future a wise conservatism will give an approval for operative measures upon a very considerable class of invalids, now usually permitted to drag out a more or less wretched life of suffering I would, however urge the limitation of the operation to the practice of men who have equipped themselves in a special manner for this class of surgery, since it is not alone theoretic knowledge that he must master, but more especially a technic that shall make him at once an artisan and an artist

THE INDICATIONS FOR PLASTIC SURGERY UPON THE CERVIX UTERI, TRACHELOPLASTY, WITH A NEW METHOD OF OPERATING.

Presented to the Section on Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY H P NEWMAN, A M, M D

CHICAGO

The operation known as trachelorrhaphy or Emmet's operation, has been in vogue for thirty-five years It has had a brilliant history and has won honors for the originator wherever gynecology is practiced, but like many good things it is not only capable of improvement, but has of late been quite generally superseded by operations in the nature of amputation, plastic work looking toward removal of diseased tissue, restoration of organic function, and remodeling of the cervix to as nearly normal outlines as possible These operations are commonly known as amputation of the cervix, but only for want of a better name, since it suggests the crudeness of the former excision of the neck of the uterus, and in no way conveys all that is comprehended in the newer work There is a wave of interest abroad concerning these improved methods, and many reports of admirable work are being made in foreign journals In our own country Emmet himself concedes that his original operation for pathologic conditions following laceration has had its day, and suggests for it honorable retirement to a few well-selected cases On pages 351-2 of the *Am Gyn and Obstet Journal*, Vol ii, 1897, he says "Since the writer's attention has been drawn more particularly to the subject of amputation of the cervix uteri as a necessary operation after laceration, he has realized that a very important change for the better has taken place within the past twenty years in the practice of obstetrics As the custom has now become a general one to employ every antiseptic precaution in obstetric practice, when laceration of the cervix occurs the efforts of nature thus assisted are sufficient in all but the worst cases to fully repair a very large proportion of tears The writer [Emmet] has also recognized the fact that within a few years past a comparatively smaller number of this lesion which need 'Emmet's operation' for repairing the cervix are now seen in practice The condition has become directly reversed within a few years past, and *now*, with but few exceptions, amputation is the proper means to employ 'Emmet's operation' fully filled its place under the then existing circumstances and still does so whenever indicated, but the author (Emmet) now offers through the publication of this paper, an equally original operation (amputation) for the relief of pathologic laceration of the cervix as it is now met with " Elsewhere in the same article under the title "When to Amputate in Preference to Repair of a Lacerated Cervix by the Usual Method," Dr Emmet says "For many years I held the opinion that it was possible, in almost every instance by careful local and general treatment to restore in time the lacerated tissues to so near the normal condition, that when the operation had been properly performed complete restoration would eventually take place with the result of bringing about involution of the uterus But I am now of the opinion that there are exceptional cases to this rule, where under certain conditions it is better surgery to amputate a portion or the whole cervix, eased tissues are completely removed and the wound afterward treated in the manner I shall describe"

While agreeing with the gifted author as to the desirability of the amputating operation, I claim that that mode of procedure is most excellent which requires least preparatory and after treatment and which exacts least in the way of time and patience from patient and physician There is a reaction against the tedium of routine local treatment that bids fair almost to go too far and abrogate it altogether It is a detriment to any patient to be subjected to prolonged topical treatment It has the tendency to establish the habit of invalidism, and to fix the attention inward, which is not a healthy stimulus to recuperation I have for some years sought to do operative work of such a character that as much as possible may be accomplished at one sitting, and the patient led to expect prompt recovery and encouraged to consider herself well and free from bondage to the gynecologic chair My results have so far been satisfactory, and it is to call attention to a method of cervical operation which meets these requirements that I have selected this subject My manner of operating differs materially from any so far described, and possesses certain advantages which I hope will commend themselves in comparison with existing modes As yet, there is no unity in choice of technique Dr Von Ramdohr said recently (*Am Gyn and Obstet Jour*, page 711) "As long as there are twenty-five methods of doing things none of them is good" This has a measure of truth in it, but the progress of surgery is marked by the passing of modification after modification of good methods, and only in such a way can perfection be reached

The poor results complained of by some good operators with amputating operations, I believe to be due to faulty technique That is to say that following the older methods of Schroeder, Emmet, Pozzi and others so far described, does not attain what is desired, because these methods through inherent faults do not meet the indications The following criticism is made by Dr A Palmer Dudley of New York [1] "In closing the wound one is very apt to narrow the canal to the extent of obstructing the escape of the normal discharges from the uterus, thereby injuring the woman instead of benefiting her Many here can recall cases in which, before operating for laceration of the cervix, they could recognize no disease of the uterine appendages while afterward disease developed Why? Simply because in repairing the cervix they closed it, prevented the normal discharge from the uterus, induced continual passive congestion of the endometrium, and the disease then traveled up the tubes"

Early in the history of the operation Pauly is said to have declared that "Of all surgical operations the excision of the neck of the womb has hitherto been the most murderous"

Improvement in technique in many quarters has advanced the operation rapidly in favor, and it is due to the literature of gynecologic surgery that such progress should be duly reported In giving a description of my own method, I wish to touch upon the indications for which it is used, and to call attention to the development of opinion in this regard

Dr Thomas, in the fourth edition of his work on "Diseases of Woman," published more than two decades ago, gives as indications "Malignant disease, great enlargement from cervical hyperplasia, longitudinal cervical hypertrophy, conical and projecting cervix and granular or cystic degeneration of intractable character" I have already spoken of the manner in which present authority sanctions its use in cases of laceration and in addition we now consider chronic metritis and cervicitis, certain forms of displacement, what is known as congenital elongation or infantile uteri and stenosis as calling for such operations Concerning the latter I find this comment in Gould's Year Book for 1898, page 534 "True cervical stenosis is a comparatively rare disease, it exists most often in the mind of the physician"

Notwithstanding this formidable comment upon a former paper of mine presented to this society, a large experience in the reality of the thing only confirms me in the opinion that cervical stenosis, whether of traumatic or congenital (?) origin, is yet a potent factor in the etiology of much pelvic pathology and an indication of radical error in the hygiene and growth of women

What is known as congenital stenosis is rarely the result of embryonic divergence, but rather persistence of the infantile condition through lack of proper development at the developmental period

In advocating amputation of the cervix for inflammatory conditions L Touvenaint (France) says "The curette, which gives excellent results in chronic corporeal endometritis, is altogether insufficient in cervical endometritis The operation gives brilliant results preceded by curettage We say 'preceded by curettage' because it is rarely the case that inflammation of the cervix has not been propogated to the cavity of the body, and the endometritis become general It has certainly been established that amputation is the operation of choice" He further says "Amputation of the cervix is not done solely for the sake of removing a part of the organ, it possesses also the advantages of inducing profound modification in the vitality of the entire uterus, so that this undergoes a veritable involution" Mundé, in an article on trachelorrhaphy in 1889, said "When a superficial layer of an organ which is affected by hypertrophy is cut off, a marked tendency to diminution in the bulk of the remaining tissue shows itself' Curettage alone can not accomplish this result, although it can do much, and in connection with excision is a valuable adjunct Not only the cervix, but its mucous lining differs from that of the uterus above in essential particulars, and chronic inflammation creates a dense, firm tissue with deep glandular involvement which only a sharp curette thoroughly used can remove Such removal is apt to result in constriction of the canal amounting to a severe stenosis or even atresia unless followed by tedious and objectionable after-treatment As I have said, the ideal operation should attain restoration of physiologic as well as anatomic conditions, and with the smallest expenditure of time and the least possible manipulation

The following are details of the method which I have found meet these requirements better than any of which I know The patient, prepared as for any minor gynecologic or plastic surgery, is placed in the lithotomy (extreme dorsal) or Sim's position, and the cervix drawn down with the bullet forceps or the double tenaculum The cervix is dilated and the uterus curetted in the usual manner Curettage is used only when the indications for its employment exist, but these are so constant as to make it virtually the rule The blades of the bullet-forceps are then reversed and replaced within the cervix so that their points are directed laterally from within outward By using them in this manner traction is made upon the inner area of the cervix leaving the anterior and posterior walls free for making the flaps The cervix is now transfixed by the knife here exhibited, (Fig 1*a*) and a clean cut made from above downward, first in the posterior lip (Fig 1)

---

[1] Tr Gyn Soc Vol xx, page 305

The anterior lip is transfixed in a similar manner about 1 cm or 1½ cm in front of the other and cut in the same way

The intervening plug of diseased tissue is now removed by a single cut or two of the curved scissors, the bullet-forceps having been changed to a lower position to allow of this (Fig 2) If the flaps have been properly made they will now fall together, (Fig 3) and inward, so as to assume the appearance of a normal cervix, and will require only the simplest suturing to keep them in this position The first suture is passed through the center of the anterior flap a centimeter or more from its cut edge and brought out about three fourths of a centimeter within the cervical canal Two parallel stitches are now placed at each angle of the cervical canal Silkworm gut is the suture material which I commonly use

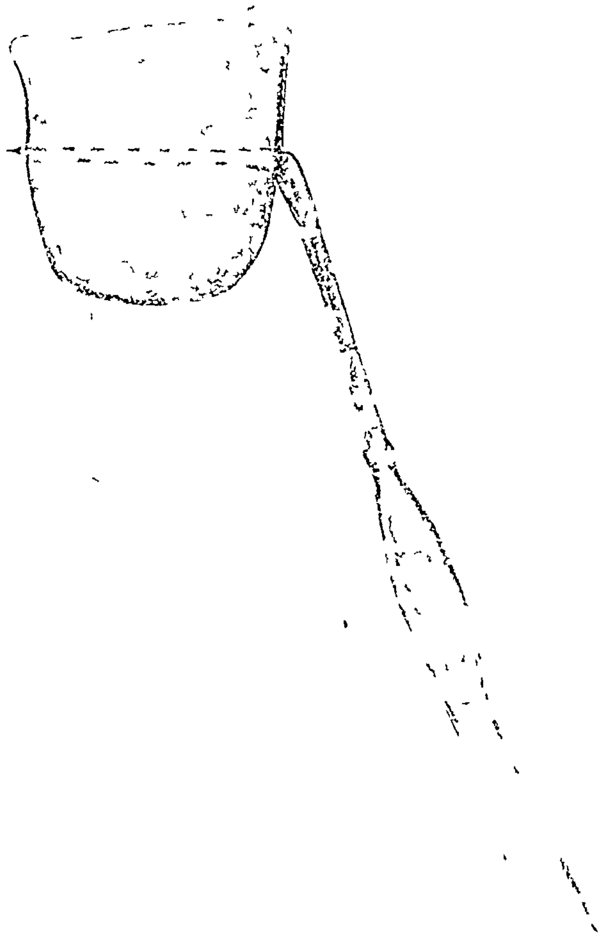

Figure 1

The posterior lip is similarly treated except that it is somewhat easier in this situation to pass the sutures from within outward rather than the reverse as in sewing the anterior lip Two sutures are now passed, as in trachelorrhaphy through the outer angles of the wound, which gap slightly after the turning in of the flaps For nice adjustment of the stitches and for ease in removal I am in the habit of treating them as follows In tying the sutures one end of each is left long, and these long ends are grouped by tying them together according to their location The three anterior sutures form one group, the three posteriors one group, and the two lateral sutures are tied together a pair on each side, making four groups in all (Fig 4)

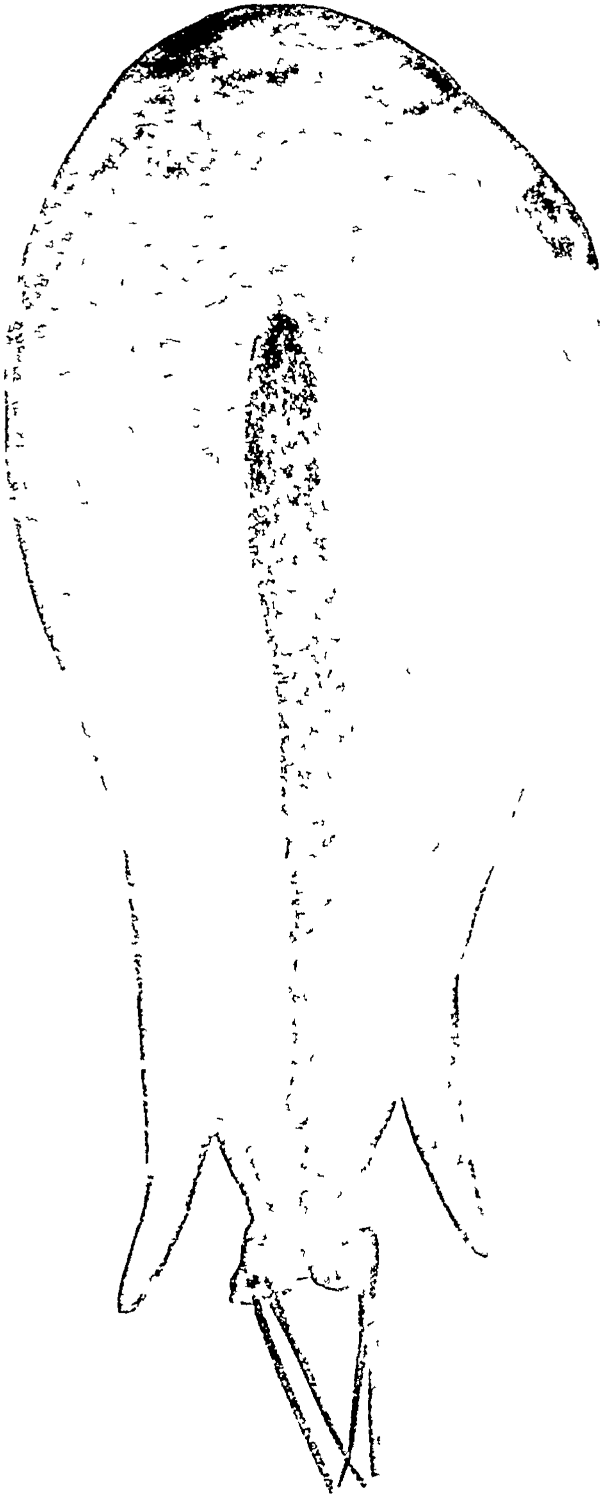

Figure 4

A uterine tampon of iodoform gauze or wicking is now inserted by means of this forceps and tampon carrier A projecting strand is attached to the vaginal tampon (also of gauze) in [illegible] that both may be removed without undue [illegible] th parts If no accessory work is done the usual perineal dressings are applied and the patient put to bed

The external genitals are bathed with antiseptics after micturition but no douching of vagina or disturbance of tampons is allowed until the second or third day, when the entire tampon is removed and not replaced Vaginal douches of 1-4000 bichlorid are then used twice daily The sutures are removed at the end of two weeks, when the patient can be up

The advantages claimed for this method of operating are 1 The quickness and ease of operating by the knife here presented, the manner of making the flaps, transcending in certainty and safety of execution the ordinary methods of excision 2 Clean, smooth-cut surfaces which are obtained without haggling of tissues, always most desirable in plastic surgery 3 The easy approximation of flaps and the avoidance of all hemorrhage beneath them by deep placing of suture and compression of the flaps 4 The accurate approximation of mucous membrane to mucous membrane thus avoiding granulating surfaces, formation of cicatrix and constricting of the canal This feature, which obtains also in Schroeder's operation and modifications of it, is of great importance and a decided advantage over trachelorrhaphy, especially where the entire cervical mucous membrane is removed 5 The certainty of obtaining a permanently patulous canal and a well-formed cervix with pronounced reduction of the hyperplastic uterus 6 The simplicity of the after-treatment

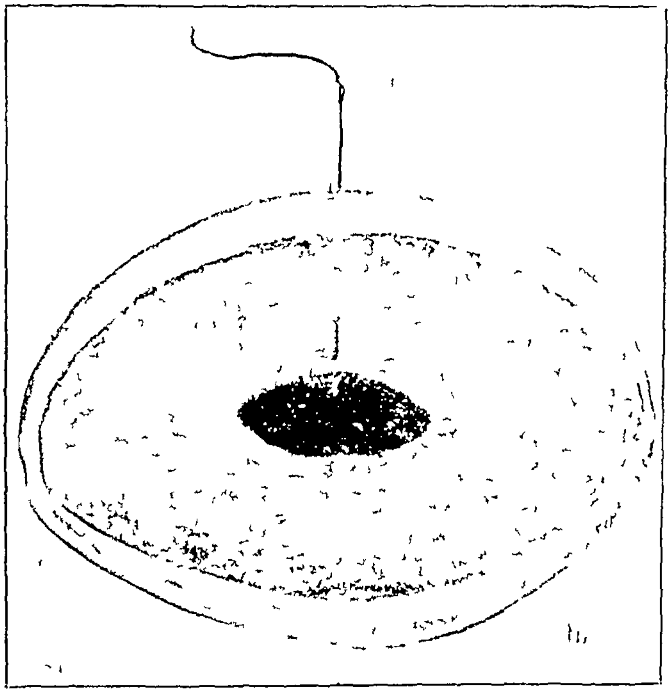

FIGURE 3

I would urge the necessity in doing plastic gynecologic work of fortifying it by doing all accessory operations at the same time The neglect to do necessary complementary operations brings frequent failures The operation I have described is seldom called for alone While it will often correct a simple displacement of the uterus due to inflammatory conditions with increased size and weight, by correcting the lesion of the cervix and accompanying metritis and stimulating involution, it is not to be advocated as a substitute for the Alexander or other suspensio-uteri procedures It will not restore the proper sustaining power of the pelvic floor, but it will be in many cases a valuable adjunct to any operation undertaken for these conditions Dr E E Montgomery says "When a condition is due to lesions during the delivery of the patient, we have a large heavy uterus In any case, in order to restore the patient to a normal condition the first aim should be to reduce the size of the organ This is best accomplished by amputation of the cervix The metabolic changes which take place as a result of the operation and the rest in bed will lead to a considerable reduction in size "

Besides correcting existing lesions and encouraging a return to the normal state it may be a determining factor in preventing the progress of malignant disease and the extension of infectious or inflammatory conditions to the adnexa The cervix is an etiologic factor in many diseases, it is a storehouse for infectious germs, it is the portion of the uterus which suffers most from maldevelopment at puberty, thus causing dysmenorrhea, sterility and concomitant evils, is most frequently injured in childbirth, so that until preventive medicine shall have succeeded in eradicating the more common causes of cervical diseases this organ will continue to offer wide opportunities for plastic surgery of the most careful and progressive kind

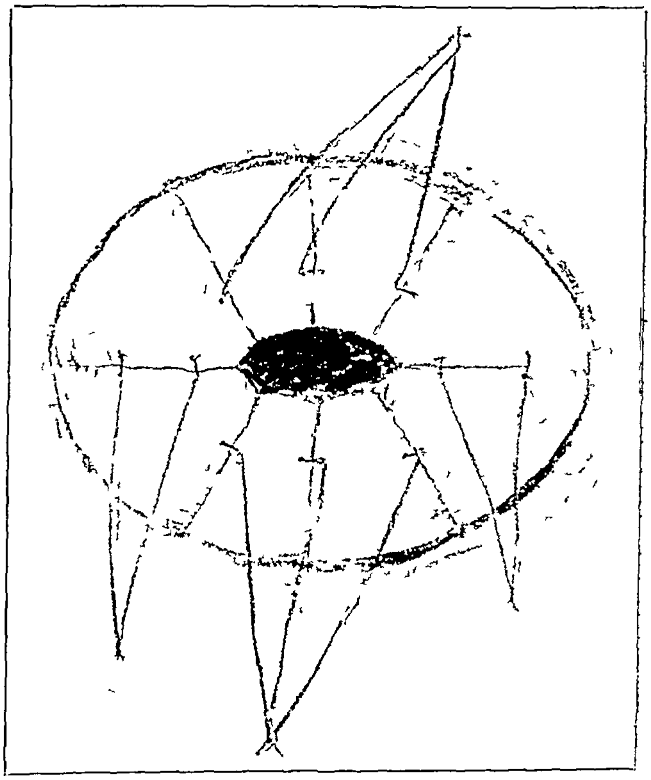

FIGURE 4

In conclusion, I would offer a suggestion as to the nomenclature of the operation *Amputation of the cervix* is as much too narrow a term for such work as trachelorrhaphy is too broad to be monopolized by the operation devised by Dr Emmet Much plastic work upon the cervix might be known as trachelorrhaphy but since this name has been applied for so long to one class of methods exclusively, we are forced to find something more distinctly descriptive for the newer work

Amputation conveys the idea of taking away of an organ, whereas this work is really conservative, plastic surgery, nothing is removed but diseased or adventitious tissue, and I suggest that it be designated in future by the expressive and inclusive term *Tracheloplasty*

ANTERIOR COLPOTOMY WITH REMOVAL OF ONE OVARY AND BOTH TUBES—VAGINAL FIXATION

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual meeting of the American Medical Association held at Denver, Colo , June 7-10, 1898

BY WILLIAM N SWIFT, M D ,
NEW BEDFORD MASS

Mrs L R , aged 21 years, married two months Probable gonorrhea two years before, since that time, more or less pelvic pain and very marked pain at menstrual periods Since marriage has had great pain across lower part of abdomen Coitus so painful that it became impossible Examination showed uterus much enlarged, very sensitive, retroflexed and somewhat toward the left side Enlarged tubes felt on both sides Operation, Aug 9, 1897

The bladder was separated from the uterus without difficulty Plica opened with scissors Extensive adhesions over the fundus of uterus and tubes The uterus was seized with double hooks and delivered through the wound with some difficulty The left tube and ovary were firmly adherent The tube was freed from adhesions and on being opened was found to be entirely disorganized and occluded It was removed; but the ovary was left as it was—normal The right ovary and tube were bound down by strong adhesions The ovary contained one large and many small cysts On section, it showed no normal tissue The tube was also much thickened, and both ovary and tube were removed The uterus was fixed by three silkworm gut sutures through the vagina, peritoneum and uterus itself, then peritoneum and vagina on the other side After these sutures were put in place, the peritoneum was sewed up with a continuous catgut suture, and later the wound in the vagina After coming out of ether, the patient showed no symptom of shock She passed urine on the morning of the second day Examination at present shows no tenderness over scar in the vagina Uterus small, in normal position, not tender Some tenderness over left ovary, which can be plainly felt Patient feels well and has worked since two months after operation Coitus has not been painful Has menstruated regularly, with only at times slight pain over region of left ovary

There are several points in this case that are interesting First the question of abdominal or vaginal section in such a case The chief advantage of the vaginal route is that it is a much less serious operation than abdominal section There is no abdominal scar with risk of hernia The patient has much less discomfort and pain immediately after operation She can turn on her side at once and is usually up in two weeks Another great advantage in vaginal section is the ease with which any operation can be done on the uterus, tubes or ovaries, after they are delivered A small vagina makes the operation difficult even with lateral incisions A fixed uterus that can not be drawn down at all makes the operation impossible

The method of opening the peritoneal cavity which I employ is, practically the one described and practiced by Professor Duhrssen of Berlin The parts are made as aseptic as possible The cervix is then dilated, curetted with a sharp curette, afterward with a douche-curette, and washed out with corrosive sublimate solution (1 to 10000) The anterior lip of the cervix is then seized with the fixature This instrument, as used by Prof A Martin, consists of a stout sound behind and a pair of stout double right angle hooks in front, set on a broad surface The sound is inserted into the uterine canal, the double hooks into the anterior lip of the cervix, which is compressed between the two The uterus is then brought down as far as possible and held forward An incision about half an inch long is then made through the vaginal mucous membrane at the upper border of the anterior lip of the cervix One must be careful not to make this incision too high up, for in pulling down the uterus the bladder is displaced and may be wounded This incision is prolonged with scissors about half an inch on each side A double tenaculum is put on the vaginal mucous membrane at the center of the incision, and traction made upward The bladder is then separated from the uterus by the finger, aided at times by the closed points of the scissors

It is important to carry the dissection well out on each side so as to have the ureters as well as the bladder out of the way By keeping close to the uterus there is no danger of wounding the bladder This dissection is carried as far as the internal os It is a mistake to strip off the peritoneum from the uterus farther up than this point The fold in the peritoneum may be felt by the finger against the anterior surface of the uterus, and in most cases may be seized between the thumb and finger An artery clasp is then put on the peritoneum and the peritoneal cavity opened by a small snip with the scissors, as near the uterus as possible Artery clasps are then put on each side of the opening in the peritoneum and the bladder dissected away from the peritoneum still farther As the bladder is pushed away, the peritoneum is slit up and clamps put on each side as guides A pair of double hooks are put on the vaginal mucous membrane about half an inch below the urethra The middle point of the vaginal mucous membrane in the transverse incision is seized with forceps Traction is made with both instruments and the ridge made in the mucous membrane is slit up with scissors The triangular flaps of vaginal mucous membrane formed by the transverse and longitudinal incisions are then dissected away from the bladder This usually peels off easily with the shut points of the scissors If vaginal fixation is to be done the sutures are then inserted on each side through vaginal mucous membrane and peritoneum I began by using silkworm gut, but since my first two cases have used catgut the silkworm being rather troublesome to remove This incision gives a wound extending from the cervix to the urethra and laterally about an inch on each side of the cervix

The examination of the uterus and adnexa is [illegible] made The uterus is then seized with stout double hooks—I much prefer right angle hooks, as they do not pull out so readily The fixature is removed and the cervix pushed back with the speculum The uterus is then delivered through the wound, any adhesions being separated at the same time with the finger When the uterine tissue is soft the double hooks may tear out several times before the uterus is finally delivered The first hooks inserted are usually too low and the uterus has to be seized several times before it is pulled out In this manipulation the uterine tissue may be a good deal torn The tears should be at once sewed up with a fine needle and catgut No ill effects come from these so far as I have seen This gives ready access to the uterus, tubes and ovaries, either for their removal or for the excision of diseased portions The tubes may be probed, and small cysts of the ovaries opened and curetted After whatever is indicated has been done, the fixation suture on each side is passed around the round ligament at its base, close to the uterus The uterus is then replaced and the end of the fixation suture on each side is passed through the peritoneum and the vaginal mucous membrane The rent in the peritoneum should then be united with a continuous suture of fine catgut If this is done no raw surface is left, and the adhesions holding the uterus forward will only be between the two layers of peritoneum The wound in the vagina is then sewed up with a continuous catgut suture Amputation of the cervix may be done if indicated Finally the fixation sutures are pulled tight and tied

The retention of the left ovary when the tube was removed is an interesting point in this case I am being constantly more impressed by the importance of the general nervous disturbance that follows the removal of both ovaries in comparatively young women The mental effect in these cases is sometimes very marked The woman often regrets the operation even when she has relief from much pain I have seen many cases of marked mental depression following castration The vasomotor disturbances are usually very striking and the patients suffer very much from them

If it is possible to spare the woman all these ills by leaving even a part of an ovary that is healthy, ought it not to be done in every case? My case shows that when an ovary is left and both tubes are removed, menstruation goes on with little discomfort I am convinced that leaving the ovary has made an immense difference to the well-being and happiness of this woman

---

SOME OF THE CAUSES OF NERVOUS DISTURBANCES

Presented to the Section on Obstetrics and Diseases of Women at the Forty-ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10, 1898

BY JOSEPH EASTMAN, M D
INDIANAPOLIS, IND

Mr Chairman and Gentlemen —I would rather this afternoon be an attentive listener, and be instructed, than attempt to instruct I was much pleased with the idea of uniting specialties rather than subdividing them There is certainly a great advantage in reciprocity in connection with the specialty of neurology and that of gynecology I have this conviction very forcibly impressed upon me every day when I am at work, because of the extreme difficulty encountered in determining whether, in a given case, the disease from which my patient suffers is a local expression of a general neurasthenia, or whether the neurasthenia is the expression of a local pelvic condition The title upon the program is a little different from that which I gave the Secretary I said I would speak of the causes of some pelvic diseases which had to do with nervous conditions It is not by any means certain, as has been supposed, that every ovary which had prominent upon its surface a Graafian follicle, when removed, was cystic Some practitioners would have us believe that the uterus and ovaries produce nearly all pelvic disturbances There are other causes to which I shall refer The relation of uterus and ovaries to this subject has been thoroughly gone over by those who have preceded me

In a very able article written by my friend, Dr Etheridge of Chicago, published some months ago, he shows conclusively that a lacerated perineum, although so slight as to be almost imperceptible, does in many cases continue to so disturb the nervous centers that decided neurasthenia may result He shows also very conclusively that repair of some of these perinea materially benefits the patient, and in many cases cures neurasthenics who have passed through the hands of other specialists, who could detect nothing of the kind I will couch my words in as modest language as I can, yet I hope that none of the lady physicians present will think me immodest when I speak of such things as concern the happiness of women, women who are the life and peace, and joy and happiness of our homes, and such conditions as send women not only to the gynecologist, but to the insane asylum and to the grave

Dr Thomas, in his work on "Diseases of Women," speaking of some of the sequelæ of lacerated perinea, makes a remarkable statement As among the things which may result he speaks of impaired sexual gratification to the male in the act of coition Why a man of his great intellect and colossal experience should not have called attention to the fact that the same condition would have a worse effect upon the woman than upon the male, I do not know Because of the lack of perineal support and loss of vulval constriction the male organ is not brought against the erectile labia minora and sensitive structures in the anterior angle of the vulva By carefully inquiring of my patients from time to time, as opportunities have presented themselves for a number of years, I have been much gratified to have women of education and refinement tell me in a modest way that the sad old experience and great sorrow had passed away since a perfect perineum had been produced, according to the method spoken of by Dr Haggard this morning—restoration of the vulval constriction and restoration of the perineum I could cite perhaps twenty or thirty cases where I have positive information on this subject, in which women were continually left with the sexual impulse excited, but not relieved, unless by masturbation, and this has been completely overcome by restoring the perineum I have some other experiences in connection with the same subject which are worth citing

Some years ago a gentleman in Berkeley, Cal, bearing my name, cut out a section of the pudic nerve for clitoromania He reported his case as cured, but also stated that prior to operation both ovaries were removed The oöphorectomy had failed to effect a cure Following his operation, I cut out a section of the pudic nerve in a given case, and for a time I believe the patient was better, although she had gone on so far as to be a decided epileptic After a period of three years I find that I have done no good whatever, and the patient is not well My second operation was made upon a patient where the ovaries had been removed with no beneficial results at all I had the pleasure only two weeks ago of seeing this young lady, who was brought from the South She belongs to a family of wealth, education and refinement, and had become a monomaniac for some reason (perhaps, as I believe, from an inflammatory condition of the pudic nerve) Before coming under my observation her ovaries were removed by a physician in Buffalo, N Y Five years elapsed and no good had come from the operation After taking out a section of the pudic nerve, I found to my satisfaction two weeks ago that she is now perfectly well and entirely restored mentally Her health was good enough physically before A careful examination of the parts showed that they were in an almost normal condition instead of being hyperemic and hyperesthetic, as they were at the time I operated This was one of the most gratifying results I have ever had Those two cases which have come under my observation, together with the case of my namesake, make it conclusive to me that the removal of the ovaries preceding the operation of taking out a section of the pudic nerve was essential to overcoming the condition

One of the gentlemen who spoke here this afternoon referred to the cure of insanity by surgical procedures I had in my experience the case of a young lady who was the head teacher of one of our city schools She was confined in an insane asylum one year, and then removed from the asylum as incurable Upon careful inquiry I found that an intense head ache came on at the time of the menstrual period This had gone on from bad to worse until insanity had resulted In her case I found everything in the pelvis absolutely normal except one Fallopian tube, and that was kinked very sharply, and its lumen completely obstructed The removal of this tube and ovary upon that side has completely restored her to health Here was a case under the treatment of the best neurologists for a nervous condition prior to her becoming insane, and yet she was ultimately cured bv a simple surgical procedure I merely cite this case as an instructive one in connection with the point the gentleman mentions

For a number of years I have been in the habit of inquiring about the vermiform appendix I have in some of these cases opened the abdomen, searched for the cause of the nervous disturbance, and, finding only disease of the appendix, removed it the nervous condition gradually passing away As to whether it was the psychic effects of the operation, I am not prepared to say I believe, however, that if we look up the literature of the subject we will find those who speak of epilepsy as a result of intestinal irritation I recall one instance In Quain's medical dictionary it is said that disturbance of the mucous membrane of the intestinal tract in children may result in the production of epilepsy and other convulsive diseases If this little appendix is an incubator wherein all manner of germs may produce a catarrhal condition and a point from which nervous disturbances are likely to emanate, surely it is to be considered in connection with reflex pelvic disturbance

At the same time there is another condition which I have found to be worthy of attention in more cases than one, and it is a point which has been overlooked I refer to coccygodynia I believe it to be the imperative duty of every gynecologist, and neurologist for that matter, in making an examination, to pass the finger into the rectum and carefully examine the coccyx It is well known that the coccyx may be bent forward by falls in childhood or be broken backward by the fetal head in childbirth This point alone has been sufficient to enable me to find in many cases a condition from which patients could only be relieved by the removal of the coccyx I recall one case in particular she had her ovaries removed, she had been in a sanitorium under the best of care, was given massage, baths, etc , for a period of nearly one year she was declared to be incurable by one of our best physicians She recovered within four weeks from all nervous disorders after the removal of the coccyx While I had taught anatomy for seven years I had forgotten the exact relation of the coccyx to the ganglion impar Getting down Gray's Anatomy, he uses these simple words "it is located on the coccyx" Then, we have, as it were, an electric button placed at the lowest point of the spinal column which may cast its current upward through the sympathetic into the great central ganglia within the brain or into other parts connected with the pelvic organs In this connection I must express my belief that it is very rare indeed for any local condition to produce the so called reflex nervous phenomena in an individual who is not neurasthenic and whose nerves have the proper affinity to attract from the passing blood stream, Lecithin, the material provided for nourishment of nerve cells In nearly all cases of nervous reflexes there is a pre-existing tendency to neurasthenia, otherwise the reflex cause would only be a local condition producing its local phenomena, and would not produce the usual nervous phenomena so often accredited to local reflexes I have not in my experience seen local conditions in the pelvis produce the general nervous disturbances so often spoken of It is absolutely necessary, as I understand it, in many instances where we operate for pelvic disease and the nervous system is involved, to prepare the patient by treatment for neurasthenia and supplement the surgical procedure with appropriate treatment for the neurasthenic condition by the neurologist Hence our gratification in meeting with the neurologists this afternoon

There is a class of women who come to us complaining of nervous phenomena They want to be everything but their present identity everywhere except where they are now in some one's company, present company always excepted They have been to the neurologist, and they go to the gynecologist and undergo formidable operations with a heroism unparalleled in history yet, after all there is some unhappy mental condition, they are living in some sort of mental torture there is a skeleton in the closet They have not loved wisely They have not married the one they loved

> Their hearts do break and show no sign
> Save whitening lips and fading tresses
> Til death pours out its cordial wine
> Slow pressed from misery's crushing presses
>
> If singing breath and echoing chord
> To every silent pang were given
> What endless melodies were poured
> As sad as earth as sweet as Heaven

If we could only get at all of these

tions we might lay down our scapels and leather bags, there might be some way of curing or relieving such individuals of their trouble and sorrow

But of all the cursed and damnable causes of pelvic disease and neurasthenia, the horrible means to which women resort to prevent themselves from having children must be considered My friend, Dr Price, touched on this subject this morning, and it will not need much more touching up after he has handled it The thousand and one methods of preventing conception, the mental torture that they continually undergo for fear they will conceive, are frightful to contemplate By and by, they are, perchance just as wild and crazy to have children, when all of the delicate functions participating in conception and motherhood, have been so impaired, and the pelvic organs so destroyed or diseased, that conception is impossible Then, too, there are the damnable methods of procuring abortion I heard an explanation only recently why extra-uterine pregnancy was so common, and it was this, that the fetus even in its smallest form had become shy and hid away up in the Fallopian tubes to escape having its eyes punched out with crochet needles and septic probes of "quack" doctors (Laughter) There is in my judgment no one thing which is to-day contributing so largely to the deterioration of womankind and ultimately to mankind, as the damnable methods of the prevention of conception and the procuring of abortion

NERVOUS AND MENTAL DISEASES FOLLOWING PELVIC OPERATIONS

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7 10 1898

BY HAROLD N MOYER, M D
CHICAGO ILL

The topic assigned to me is a narrow one, namely, the nervous and mental diseases or changes which follow pelvic operations in women The purpose of the inquiry is to show if there is any difference in the nervous and mental effects which follow operations upon the pelvic organs from operations done on other parts of the body or surgical operations in general It would be easy to discuss this subject from one's individual experience, but it would be exceedingly narrow The observations that come to any one man are certainly few as compared with those that come to a large number of operators, so that I shall not relate individual cases, but will draw conclusions so far as I can, from the literature which is accessible to me and the material which I have collected The literature is disappointingly deficient in many respects Reported cases of the nervous and mental changes which follow operations in general are very disappointing, especially when studied from a statistical standpoint There have been a large number of studies made and cases collected of the nervous and mental phenomena which follow operations in general, but when we come to analyze this material we find that it is so varyingly expressed in different groups and in different tables, that an adequate comparison of a considerable number of cases is well-nigh impossible If you think for a moment, you will see that the subject is one so complicated in its nature, that it scarcely lends itself to statistical treatment at all If you remember, for instance, the widely varying opinions as to the efficacy of a particular treatment of typhoid fever, or indeed so recent a subject as the antitoxin treatment of diphtheria, a disease which is comparatively the same in all individuals, being of short and very nearly the same duration, it would seem as if the statistical method would throw abundant light upon the value of these treatments and would serve at once to settle the question as to their value But as a matter of fact, it has not done so conclusively in all respects When we come to consider the subject of operations and their effects you can see that the increased factors which we have to consider constitute such a varied problem that accurate, clear and concise conclusions can not be drawn I can only bring to you today such general statements and such general conclusions as I myself have arrived at, without being able to give in figures the basis upon which they rest

The first question which naturally presents itself is this Is there any difference between operations upon the pelvic organs of women and operations in general? If you examine the statistics you will be at once struck with the number of cases which are operated upon for pelvic disease, which show insanity, neurasthenia and other nervous troubles following operation and probably resulting from it Some writers have come to the conclusion that these operations are peculiarly liable to be followed by such phenomena, but if you come to analyze the cases more closely, you will find that operations are performed upon persons whose general health is greatly impaired The great majority of them are very much reduced by a long history of illness prior to the operation The operations in themselves are many times prolonged, and a by no means infrequent condition is the one of infection, a slow poisoning of the system for which the operation was undertaken Those necessarily are apart from the operation itself, and they furnish a fruitful soil upon which nervous troubles and insanity are built In order to get some sort of basis for comparison, I have taken fifty cases of opertions upon the prostate and bladder I have thought there might be some comparable relation between the pelvic organs in the male and in the female The operation was on the same part of the body and frequently accompanied by ill health, and often in the male by infection I compared fifty cases, excluding all those in which there was marked disease of the kidney, and I found that the nervous and mental effects following operations which might be attributed to the operation per se, were much greater in the male than in the female Taking all factors into consideration, operations upon the female pelvic organs are not attended with more nervous disturbance, such as neurasthenia or insanity, than are operations in general surgery

The character of the mental disturbance which may follow operations is substantially the same, whether the operations are done upon the pelvic organs or upon other parts of the body The great bulk of them fall within the class of neurasthenia, or that condition which is described by alienists as primary confusional insanity These two conditions seem to be the great predominating mental and nervous states which follow operations

Again, I tried to study the question as to the particular character of the operation, and as to the part that was involved in the operation, and to find out if that had a bearing upon the question I am unable to offer any conclusion on this point Those operations which include the ovary or Fallopian tube, and which are followed by the artificial or early menopause, were carefully studied, and I particularly addressed myself to the question as to whether there was any difference between the nervous phenomena of the artificial or induced menopause and the nervous disturbances which accompany the menopause at the ordinary time of life. My conclusion is that there is no essential difference and that they are practical, so far as nervous phenomena are concerned.

Another question is: Whether the removal of the ovary added an additional factor, in the sense that there was something taken out of the economy, if you please, by which there was created an unstable or peculiar nervous state, something that was comparable to the removal of the thyroid gland or an internal secretion cut off, and whether there might be mental phenomena growing out of the removal of the ovary distinct in their characteristics from the artificial menopause? I have no conclusions to offer upon that phase of the subject. I have not formed an opinion as to whether that is so or not, as the evidence is very conflicting. It may or may not be. Certainly, so far as the effects of operations are concerned and so far as my studies go, there seems to be a practical point in this, that the ovary had better be left in, or a part of it, if possible, and there is also sufficient to warrant the deduction that resection of the ovary is far preferable to removing it, if it is possible to do so.

In conclusion, therefore, I would simply say that I have arrived at the opinion that there are no radical differences in the primary effects of operations upon the pelvic organs in men differing from the effects of similar operations in women, or indeed of operations in general surgery, and that there is a distinct and peculiar effect from the removal of the ovaries or tubes, or both, by which the menopause is established, but that that does not differ in its nervous phenomena from the menopause occurring normally at the ordinary time of life. As to the possibility of a peculiar physiologic effect following extirpation of the ovary, not attributable to the menopause, I have absolutely no conclusion to offer.

DISCUSSION ON PAPERS BY DRS. EASTMAN AND MOYER.

Dr. **Milo B. Ward**, Kansas City, Mo.—I could never quite understand how it is that we have so many differences of opinion in our profession regarding a question of so much importance as the one before us today. One physician will come before you and say that surgical interference is never indicated in neurotic troubles, and that the results are never good. That is the implication at least. Another will tell you that of very many cases that have come under his observation the majority of them, when operated on judiciously, recover entirely. We take the history of one case, for instance, in our experience and make it cover the whole experience of our practice. For instance, if I operate on a patient who I know has a nervous affection and she does not recover, I am frightened out of doing an operation for like conditions on other patients. About three years ago, when I was called upon to discuss this question in the State Medical Society of Missouri, I said then that I did not believe surgical interference was ever indicated for neurotic troubles unless the pathology was very marked, and then we operate for the pathologic condition without any expectation whatever of deriving much benefit from the operation as to mental influences. I am here today to champion the opposite of that opinion. I have had cases enough in my own experience in which relief was so perfect following surgical interference for disease of the pelvic organs and marked nervous disturbance, that I think we have here a great field for investigation and work. We are bound to admit that there is no other influence in the human economy that has so much to do with the general system as the pelvic organs in the females.

About a year ago a young lady was brought to me under the impression that she had some pelvic trouble. Her father had been told by his physician that she had epilepsy, she was a great sufferer, and it was really a pity to look at her. I examined her carefully under ether, and found absolutely no pathology in the pelvis. I stated as my further belief that an operation for pelvic trouble was not indicated and that I would put her on the improved treatment for epilepsy and watch the symptoms. After two and a half months' treatment the young lady improved, but not satisfactorily so. I made an exploratory incision and finding that the appendages were diseased, removed them. The young lady went home at the end of five weeks perfectly well and has not had a symptom since then.

I have had two cases in the last six months where I have removed the uterus for disease. In one case the appendages were removed for neurotic troubles. These patients were great sufferers constantly for weeks and months, and both of them are well today, having had no symptoms since the operation. I have been informed recently, although I can not give the author of the statement, by a physician who heard the report that in Toronto an alienist reported that a hundred and nine cases in the asylum there were subjects of various pathologic conditions, and each one had had an operation performed, and of that number about seventy five per cent. of them were sent home well. How are we going to account for that fact unless there is some relation between the pelvic organs and the general nervous system?

A few years ago I had the honor to be gynecologist for the Topeka Insane Asylum. There were two patients brought to me with the belief that something could be done for them by resorting to operative interference. One young woman had homicidal insanity, tried several times to kill herself, and was brought to the asylum as incurable. In her case I found marked pelvic disease with adhesions, and I said to the husband, "I will operate on her, although I do not believe it will do any good." I removed the diseased organs, and strange to say, that woman never had a symptom after the operation. It is three years since the operation was done and she has never had any symptoms since.

Dr. **J. T. Eskridge**, Denver—I am sure we are very much impressed with the change that has taken place during the last fourteen years. I remember—I think it was in November or December of 1883—of participating in a discussion before the Philadelphia County Medical Society on this subject. There was a distinct antagonism between the position of the neurologist and that of the gynecologist. As you can recognize from the discussion this afternoon this feeling has largely passed away. We are coming to recognize that the mutual relations of certain specialties are so strong that we must work together, if we work for the good of our patients. I feel very closely associated with the general practitioner of medicine, with the gynecologist, the laryngologist, the ophthalmologist and with the specialist of acute and chronic diseases in both male and female. I feel that every man must know something of everything in medicine and everything, if possible, of some one special subject. We find patients coming to us who complain of various symptoms. If a patient comes to me complaining with an array of nervous symptoms which have existed for some time, and I find on inquiry that the symptoms point strongly to the pelvic organs, I do not submit that patient to the expense of an examination from a neurologic standpoint, but I send her to a gynecologist and let him find out whether there is any special trouble in the pelvis first. I realize the fact that I am to do my best, and if some organic lesion exists in the pelvis it is impossible to cure the patient until the organic lesion is relieved. The gynecologists and neurologists of Denver work together in this respect. If I begin to investigate a case of nervous disease, and find there are other symptoms which strongly point to some local trouble, be it in the chest, in the nose or the eye, I invariably send the patient to the proper specialist for investigation before I try to thoroughly examine her. A neurologist should be made the broadest of all specialists. He should investigate his cases most thoroughly, but only after certain conditions are excluded. I have tried to cure certain cases of nervous diseases that presented decided symptoms of pelvic trouble. I have succeeded in many of them, but have failed in others. Now, I never try to cure a case of nervous disease, such as neurasthenia until I have excluded the possibility of local trouble in various portions of the body. Further, I believe that certain conditions depressed states of the nervous system may cause the development of symptoms in special organs of the body, [illegible] person simply in a neurasthenic condi[illegible] period of years and she may after a [illegible] trouble and a gynecologist getting h[illegible] think that she has suffered all the [illegible] trouble when as a matter of fact it vic trouble has been subsequently developed, her state of health has been depressed, other causes have acted locally and local trouble is developed

In regard to how much intra pelvic trouble has to do with the causation of nervous troubles, I think everyone who has had much experience will say that they have a great deal We can have a typic train of nervous symptoms due to intra pelvic trouble, as has been developed over and over We can bring forward numerous cases of insanity that we have seen cured by operative measures, but no cases of dementia existing over a period of years Dementia is practically incurable, that is, it is never cured by intra pelvic operations But the insanities are cured A number of cases of operations upon the body other than the pelvic organs have resulted in a cure of mental disturbances I could cite a number of cases of insanity that have been cured in this city by prompt surgical measures These were comparatively acute cases of insanity But there is a happy medium, and that is just what we are all striving for, and the nearer specialists work together, the sooner we will reach the goal We should investigate our cases from an unbiased standpoint, we should investigate them so that we can get an exchange of opinion, and I hope the time is coming when we will have other symposiums on different subjects, so that we can understand each other It would be a good thing if we could meet together in one room, but we can have symposiums from year to year and learn the views of others, although our work runs separately

Dr **JOSEPH PRICE**, Philadelphia—During the last year or two neurologists have paid quite as much attention to gynecology theoretically as we have, but not quite so much, I regret, practically If they had paid as much attention to the diagnosis of the pelvic viscera as they have to the theory of neurasthenia, they would not have appeared in print as often the last year or so, and some of the gentlemen have figured in this discussion

Intra pelvic disease in private practice and in our public asylums is largely responsible for many of the nervous disturbances found I recall a case that came under my observation some years ago, in which a woman was said to be suffering from vesical or rectal disturbance, and I was asked if I would not see her I saw her the following day, relieved a simple fissure by divulsion and returned the woman, who was lodged in an asylum, to her home She is now an active woman, and has borne a large family Dr Potter of Germantown once referred a patient to me who was wearing a spinal brace, and I think a jury mast She had been married some years ago and had never conceived She was greatly emaciated, she had all sorts of emotional disturbances aside from her physical incapacity On examination I found the uterus and appendages fixed, and where we have a fixed uterus and appendages we have occlusion with retention of fluid, pus or water—always I removed the diseased appendages, freed the uterus, and she made a good recovery She has not worn the jury mast or spinal brace since Another case A woman from Pottsville, the wife of a prominent business man, was confined in an asylum Her husband was urged to consult me, and I advised him to bring her home This he did On examination I found the appendages diseased, with occlusion and retention again I removed the diseased appendages, and the woman has made a beautiful recovery

An active practitioner in West Philadelphia brought a patient to my office some two years ago She was a young woman, 20 years of age, and she had been treated by three prominent neurologists of Philadelphia He went on to tell me that her mania and nervous disturbances were of such a marked nature that it was necessary to confine her or put her in a jacket The nervous disturbance was always aggravated at the menstrual period He asked me if I would attempt to do something for her relief She was the daughter of intelligent people in good circumstances The young woman was admitted to my hospital in a strait jacket This was removed and she was controlled by two good nurses In that case I found simply prolapse with fixation, a subject you have discussed most carefully There was also great tenderness The local conditions had been treated by general treatment, but unfortunately not by local methods I removed the appendages and she recovered beautifully She went to the country and her convalescence was prolonged by quiet and rest I do not think she has ever had a convulsion since, and she is now a devoted daughter, and goes out into society

Some years ago I did a few operations in my native State, and while visiting an institution at Petersburg, Va, I had a curiosity to know how many colored women in that asylum were burdened with fibroids I do not believe that most women who have fibroids are entirely themselves There is always more or less marked disturbance I went over the asylum and examined the colored women rapidly for one hour with fibroids and tubal and ovarian disease In some cases it would really have been difficult to have passed a catheter between the fibroid, compressing the pubic arch, and the urethra It was the saddest experience I have ever had in gynecology

Regarding nervous phenomena following operations, I am perfectly willing to admit that we have had too many post operative sequelæ and too many local lesions following our operations, but many of the operations early in the history of gynecology were imperfect and incomplete The materials were badly chosen, and are yet in many cases Very few gynecologists and very few surgeons are serving the apprenticeship they should serve For instance, I am constantly removing dead ligatures and all of you who are doing much of this work are doing the same thing Three days before I left home I did three consecutive sections One woman had had two sections performed on her While operations are done with badly prepared materials we will have all sorts of nervous disturbances and local pain until they are removed

The specialists in other departments have been very fair I have specialists who constantly send patients to me Nose, throat and ear men send patients to me and ask if there is anything the matter with the pelvic organs of their patients I examine them carefully and write them if I find the slightest lesion whatever If there is but slight tenderness and absence of adhesions of any character on the right or left side, I tell them a little general treatment judiciously directed by themselves will be sufficient and that operative interference is out of the question They follow my instructions, and the patients are willing to be guided by their counsel and treatment, and are benefited Early in the history of this subject we were probably all guilty of doing operations we should not have done, but we do not feel so badly about it because the cases were very few, and it is easier in a progressive profession simply to practice levelling

Dr **HENRY O MARCY**, Boston—Your presence during three long hours upon a discussion of this subject is sufficient evidence of the intense interest and value of it But I am reminded that this discussion should have closed with what Dr Price has told you However, there is something else to be said It is not a very great while ago that a story was told me of the late distinguished Benjamin Butler His assistant interrupted him in the midst of one of his debates to give him a point, and he turned to him and said, "When I have got through, you can rake behind" When Dr Price gets through there is very little raking to do It is said that a student in New York from the Allegheny Mountains, after hearing a discussion upon this subject by one of his professors, turned to one of his friends and said in his vernacular "I'll be gol darned, I'd rather be a moonshiner in the *mountains of* Tennessee than to be a uterus in the city of New York" This subject is by no means so new as some would have us believe I am reminded of a celebrated discussion that occurred between two most notable men sixty years ago in London Sir Benjamin Brodie and the great Watson, who wrote the practice of medicine in two volumes which we were asked to digest in our earlier days After they had gone over the case carefully, Sir Benjamin asked this great physician his opinion, and he said "Sir Benjamin, it seems to me, Sir, that it is equally good practice in medicine, as it is good practice in surgery, that if you find the offending organ, to deal with it in accordance with its real merit" That may settle altogether the question you have had so long under discussion today When you have found the offending factor it is your duty to consider it in the light of the better *knowledge* which it is our profession to possess This may settle the question in broad terms You all know that the experiences that have been related today are not alone, but that they can be multiplied in the experience of every individual present I am glad to tell my friend Dr Ward, that it was none other than the distinguished Dr R M Bucke of London, Ontario (superintendent of the Insane Asylum), who, as my guest less than three years ago, said he would go back to Ontario and ascertain by careful examinations made by good gynecologists how much a factor pelvic diseases pertained to the patients there incarcerated And last summer at the Montreal meeting of the British Medical Association he made the report to which Dr Ward referred, and he told me afterward personally that in more than 80 per cent of the cases there were complete cures, the patients' mental equilibrium being restored I believe that Dr Price is right regarding our asylums In Massachusetts I have asked several times that the inmates in our institutions for the insane be examined by a competent man, and I have had the requests denied It is a question that has a practical bearing I am sure there are many cases in which, after pelvic opera tions, mental troubles have been relieved Plenty of cases can be reported Here is one, for instance A woman had been married seven years and for this period was practically an invalid in bed She was brought to me 500 miles, and after the removal of the offending pelvic organ she was completely restored, she took her position in society and made her home happy Four years later she came to see me and said that she was not feeling quite well, and this time the appendix was the offender, which had been carried down by some forcible act into the pelvic structures and was adherent behind the uterus The appendix was removed and again she was restored to health

Not long since a patient in my private hospital was brought to me in a strait jacket, she had worn a suspensory apparatus so long a time that it had deformed the body She had been in one of our general hospitals for several weeks, had been examined by neurologists, and they had declared nothing could be done After a careful examination I found adherent adnexa, disease of the ovaries, removed them, and four weeks afterward the woman was walking without her jacket, and only a day or two before I left home I was informed that she was progressing rapidly This is not an isolated case, each member of the Section can multiply them in great number Take the diseases that come from pus tube and many affections of that character, and ask yourselves as to the results following surgical interference But in closing this already too long discussion, for I see many of you are tired, I would like to say this, that in all of the discussions in which I have participated I have rarely seen such equipoise of good judgment and of discrimination as has been shown in the debate to which we have listened this afternoon

Dr **Charles H Hughes** of St Louis, Mo —I believe I had the honor by invitation of Dr Marcy of reading the first neurologic paper in this country before a gynecologic body I selected, at the suggestion of Dr Marcy himself, the theme, "The Neurological Aspect of Gynecic Disease " We all sail in the same boat We work in the same field, and we are obliged to work together, we can not make any progress without it Neurology depends upon gynecology largely in the affections of women, and it is apparent to leaders in gynecologic thought that the nervous system is no longer ignored, and has not been for decades in the history of gynecologic practice by the most eminent, practical and best gynecologists of our day There is no quarrel between the average intelligent gynecologist and neurologist today, and if I had made the opening speech I should have congratulated both departments upon the wonderful growing together of neurology and gynecology, and the notable advances which both specialties have been making in the last three decades Neurology is a young specialty Gynecology antedates neurology a long way You have a longer time in which to look over past records You have committed some errors; ours are yet to be made The question we are both endeavoring to determine with scientific accuracy is when and where and how to interfere gynecologically, and when and where and how to proceed neurologically in a given case involving woman Our observations teach us that it is absolutely impossible for either of us to get along without the other and be successful practitioners of medicine We have learned, gynecology has learned, and now gynecology teaches that a neuropathic diathesis is not to be obliterated by an operation, and neurology acquiesces in the dictum of gynecologic thought It is not the intelligent, up to date gynecologists that neurologists quarrel with, but it is the intermeddler who knows neither gynecology nor neurology Neurology does not exempt a woman's pelvis from those necessary operative procedures which are so essential in the presence of disease An unstable nervous organism may be rendered stable by a judicious and timely pelvic operation The gynecologist does not cure the underlying the neuropathic, hereditary instability of the organization It is only men of limited knowledge in gynecology or neurology that make this assertion The atmosphere is becoming clarified, and we are seeing more clearly than ever before, and we are working together

Dr Price referred to a case of insanity being cured by treating a fistula When I was 22 years of age, in a military hospital, I recollect relieving a fistula and curing a case of melancholia in three weeks The neurophatic instability was there, the determining factor that produced the latent melancholia was removed and the man was restored to his normal condition That is the value of the neurologic idea of gynecic operations We do not stop upon rational gynecologic procedures We ought not in a discussion like this to attempt to make each other out culprits and disparage the efforts of the other in this work, because we as neurologists can not get along without gynecology We do not want it, and you can not get along without us, without borrowing information from neurology, nor can we without borrowing information from gynecology nor do we want to

My object in participating in this discussion is to put neurology in its proper aspect before gynecology It is the needless meddlesome gynecology that we object to it is the psychical effects produced at certain times by gynecologic procedures that are not necessary, but whenever an operation is inevitably necessary no neurologist, properly informed, dare object

Dr **S C Gordon**, Portland Me —I had the honor to be Chairman of this Section at the meeting in St Louis in 1886 The title of my paper at that time was "Hysteria and its Relation to Diseases of the Pelvic Organs," and was based upon operations that I had made from 1883 to 1886 in just this class of cases I showed from the cases detailed there abundant proof to my mind that removal of the ovaries had produced relief of the nervous symptoms, or of hysteric symptoms Before that time neurasthenia had hardly come into use We had hardly discriminated between hysteria and neurasthenia Now, some of the cases operated on and reported at that time have been neurasthenia I am not sure they were not I am sure, the neurologists of today would not have called it neurasthenia, and neurologists all admit, that neurasthenia may have a pelvic origin, and it may be relieved by operations upon the pelvis I do not mean to say, that I did operations at that time that were needless

I was called at that time, "a radical " Dr Joseph Price has been called a radical It never disturbed me very much, because I knew I did a great deal of good in this radical direction Since then I have learned a good many things, I have learned to do conservative operations upon the ovaries and tubes, and such operations have been beneficial, as has total extirpation of these adnexa But I am still a radical, and in every case where I feel obliged to remove the adnexa, I remove the uterus and all I get rid of the whole business If that is radicalism, I make the most of it I do not remove the tubes and ovaries for conditions that I once did But the point made by Dr Humiston of Cleveland is a strong one and that was made prominent by Dr Palmer of Cincinnati in a paper read before the American Gynecologic Society three years ago, namely, a sclerosed condition of the tunic of the ovary You cut the ovaries with a knife and you can cut the finger with the edge of the incision in the ovary Those are cases that no neurologist in the world can benefit, and when they have nervous symptoms connected with this condition I remove the ovaries, but I do so only after a careful examination and the conviction that such is the physical condition of these ovaries Therefore, I believe we are doing a great work in this matter We have done a great deal in this direction and we all learn from our mistakes We believe we have benefited hundreds of women by radical operations

Dr **C E Riggs**, St Paul—I think this symposium has proved of the greatest benefit We have learned some valuable facts, namely, that we are very much closer together than we really knew of If a woman has local trouble she expects to be neurasthenic or hysteric and possibly insane, that is, in extreme degree I never will forget a case I saw in the Salpetriere a little over a year ago, shown by Charcot the younger It was a woman who had a great desire to be an angel So intense was the desire for it that she went into the chapel where the beautiful pictures were with hands clasped, rising on the feet ready to soar and pierce the heavens She did rise on her feet She had an hysteric contraction of the gastrocnemius muscles, and the only one thing she lacked was wings

This feeling, that there is something particularly serious about pelvic conditions is destined along the line of suggestion to do a vast amount of harm I remember Charcot saying never, never remove the ovaries for hysteria I do not think he meant to exclude the removal of pathologic ovaries, and I am sure, no neurologist, who has looked at the subject broadly, would take any other view than that if the ovaries were the source of reflex irritation they should be removed I have in mind at the present time a woman who was said to be having serious trouble during the adolescent period and finally, not knowing whether the ovaries were exactly healthy or not they were removed, and for seventeen years that woman has been an invalid The ovaries should have been allowed to remain I think resection of the ovary in some cases would prevent many serious consequences along the line of nervous troubles that usually follow As to mental troubles it is absurd to suppose that pelvic disease can cause dementia Terminal dementia as has been said by my *confrère* Dr Eskridge is absolutely incurable There is no doubt but what local can
a neuropathic condition but when we ha
we have hyaline and fibroid degenerati
we have increased neuroglia we have
we have all of these things closing the
individual which no operation can remo

A CONSIDERATION OF SOME OF THE REMOTE SYMPTOMS AND COMPLICATIONS OF A PELVIC DISEASE

Presented to the Section on Obstetrics and Diseases of Women at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY H. D. NILES, M.D.
SALT LAKE CITY.

The existence of an intimate relationship between diseases of the female generative organs and morbid conditions and functional disorders in other parts of the body was known and appreciated in the earliest days of gynecology. The older gynecologists, guided as they were by clinical observations alone, and misled by a false pathology, based upon speculations and guesses, regarded these conditions and disorders as expressions of a mysterious, sympathetic or nervous influence that these organs, when diseased, exercised over remote parts of the body. For many years such obscure, vague and indefinite explanations satisfied the arm-chair theorist and furnished guidance and consolation to the office gynecologist and his patients. So long as our knowledge of pelvic disease was limited to conjectures suggested by the position of the uterus, the character of the vaginal discharge, the appearance of the os, etc., and our treatments were confined to applications, poultices, injections and sedatives, these unsatisfactory and untrue explanations can not be said to have been absolutely harmful. But with our present conception of the pathology and surgical treatment of pelvic diseases, it is both possible and necessary to obtain a clearer understanding of these remote symptoms and complications, and the serious consequences of overlooking and misinterpreting them are emphasized today by many a sufferer from an unnecessary, ill advised, poorly planned or neglected operation. The complaints of these sufferers not only remind us of actual errors or oversights which we should strive to avoid, but often serve unfairly as texts for remonstrances against surgical treatment in general.

Tempted and sometimes misled by the allurements of the more brilliant life-saving procedures, I believe we are prone to forget that the ultimate fate of our patients, our own reputations and the further advancement of surgery depend today more upon our correctly interpreting these symptoms and our prevention and proper management of these complications, than the devising of any newer and quicker methods of removing a pathologic specimen or of evacuating a pelvic abscess. The patient may soon forget the length of time in bed and lose interest in the size or location of an operation scar, but neither she nor her physician can banish from their minds the misery and suffering resulting from an imperfect diagnosis or an incomplete operation.

In examining a patient suffering from a possible pelvic disease, I have found it convenient and helpful to recall that the remote effects of pelvic disease may be due to the following causes:

1. *Septic infection*, ranging in virulence from puerperal septicemia, attended by chills, high fever, sweats, etc., to the mildest sepsis which may be shown by a slight headache, feeling of malaise, bad color, loss of strength, etc.

2. *Pressure upon nerves, vessels, ureters, bowels or bladder* causing neuralgias, local congestions, hemorrhoids, vesical irritation, painful defecation, constipation, partial or complete suppression or retention of the urine with resulting general symptoms.

3. *Bladder, bowel or omental adhesions*, the latter producing a chain of symptoms, due to the weight and dragging upon the stomach and colon of an adherent omentum. I believe that in women a large number of the cases described as gastro-enteroptosis may really be suffering from this cause or from colons heavy with fecal accumulations.

4. *Nervous reflexes.*—Under this head are included all those symptoms which with our present light can not be satisfactorily explained on any other hypothesis.

The wide range of symptoms capable of being produced by these four sets of causes may be advantageously considered in groups as follows:

1. All those that are due to deterioration of the blood, either by septic absorption or defect in the eliminative organs.

2. Those that are due to pressure upon the nerves or blood vessels of the pelvis. Among the pressure symptoms are also included all those non-inflammatory and non malignant hypertrophic or atrophic changes in the ovary or endometrium which by pressure or irritation of the nerves or glandular elements cause distress or functional derangement.

3. Those that are due to functional disturbances or organic disease of the stomach and intestine from omental or bowel adhesions. In this group would be included such cardiac and nervous symptoms and evidences of malnutrition as may result from gastro-enteric disease.

Given a pelvic lesion, I believe that a reasonable explanation of most of the remote symptoms will be suggested under some of the above headings, or given the symptoms indicated in the foregoing classification inexplicable otherwise, I believe that we should search the pelvis for a possible cause, even in the absence of local signs or symptoms.

The two sets of symptoms which in my experience and observation we are most prone to overlook, underestimate or misinterpret are: 1, those symptoms of a mild systemic infection from low-grade chronic inflammation, and 2, those distressing derangements or grave diseases of the stomach and intestines, that bowel or omental adhesions are capable of producing.

Arthritis, tonsillitis, headaches, neuralgias, general mental and physical depression, evidences of malnutrition and all the well-known symptoms of a mild toxemia, with or without fever, may be due to absorption from a chronic salpingitis or an endometritis that may produce but little pelvic distress. All pelvic surgeons have observed the emaciation in chronic pus cases long after the acute symptoms have subsided. Dr. Price was the first to call my attention to this wasting, particularly in the legs of such patients, and he regarded it as a symptom of some significance. My own observations lead me to conclude that as a rule the nervous system is first to feel the effects of this deterioration of the blood, then the muscular system, but any of the structures of the body may suffer to an extent that might easily divert our thoughts from the real source of the trouble. I think that when these indications of blood deterioration occur and no defect in the excretory or assimilative functions can be discovered, we may assume that they are due to toxic absorption, and in women between the age of puberty and the climacteric the most probable source will be found in the pelvic organs, just as in a man a posterior urethritis or a chronic appendicitis is the usual origin.

The stomach and intestines seem to readily adjust themselves to the changes in position and crowding produced by large tumors or pregnancy, but any interference with the functions of their muscular coat, impairing, preventing or reversing normal peristalsis, whether by direct pressure of tumors, the dragging, constricting or occluding of bands of adhesion or the action of toxic irritants, may be followed by the most serious results. Normal peristalsis depends upon perfect and regular contractions of the circular and longitudinal fibers of the muscular coats of the intestines, and as no chain is stronger than its weakest link, any band of adhesion that serves to impair the functional activity of any part, however small, of this muscular coat, must interfere with normal peristalsis. Taking this view and taking into account the frequency of these lesions, I am convinced that peritoneal adhesions rank second only to sepsis in the production of distressing and dangerous symptoms. All pelvic and abdominal surgeons who have studied carefully the many recent excellent articles upon gastroptosis, gastro-enteroptosis, dynamic and adynamic ileus, etc., must be impressed that these conditions are due, not directly to downward displacement of the abdominal viscera but to interference with the normal functional activity of the muscles employed in peristalsis and that this interference is usually due to the dragging, constricting or occluding effects of adhesions, or in rare instances to the presence of microbic or other irritants (as lead). This view is further corroborated by the well-known fact that the omentum is always quick to attach itself to any pelvic inflammation and the contraction and the impaired mobility that ensues is likely to be followed by dragging upon the colon and stomach and attended by characteristic gastric symptoms. A colon heavily loaded with fecal matter may produce the same dragging with similar symptoms. The vomiting accompanying hernia of the omentum is susceptible of the same explanation. In a large proportion of the autopsies performed upon child-bearing women, a sagging colon will be found that has produced no suggestive symptoms during life, unless chronic constipation, peritoneal adhesions or exposure to lead poisoning previously existed. I believe, therefore, that we are not justified, as a rule, in regarding this displacement, taken by itself, as a pathologic entity. The following case illustrates well the point I have attempted to emphasize and will doubtless recall other cases where the remote symptoms and complications overshadowed and obscured the original pelvic lesion.

Mrs. C., Idaho, aged 37, housewife. First seen Feb. 20, 1897. The patient, an extremely pale, anemic, emaciated woman, gave a history of having been ill for two years. During the most of this time she had been under active treatment for a grave stomach disease which was regarded by her last medical attendants as either gastric ulcer or cancer. She certainly gave a very suggestive history, viz., severe pain over the pit of the stomach, radiating to the back and shoulders, worse after eating, vomiting daily, food, coffee ground material, and at times considerable blood. She had lost fifty pounds in weight and for the past six months had been bedridden most of the time. Her diet had been soft predigested foods taken in small quantities. When the paroxysms of pain occurred the only relief she obtained was by the use of morphin and the stomach tube which had been her constant companion. There was no tumor nor marked tenderness, but the stomach was displaced downward until when distended it extended below the umbilical line. It seemed to me that in spite of this history, the length of time should exclude cancer and that we had not the typic symptoms of gastric ulcer. Vaginal examination disclosed a retroverted uterus, the fundus pressed to the right by a small immovable tumor.

On February 25 I opened the abdomen and removed a dermoid cyst, the size of a small orange, containing bone, cartilage, hair and sebaceous material. The adhesions were extensive and strong, attaching the lower order of the ometum firmly to the tumor and thus dragging upon the stomach. These adhesions were thoroughly broken up and the abdomen closed without flushing or drainage. The patient made a smooth recovery and left the hospital quite well four weeks later. I have heard from her at intervals ever since and always favorably. She eats anything and everything with impunity, has no distress or occasion to take a dose of medicine. She has regained her former weight and strength and in every way appears perfectly well.

Septic infection, peritoneal adhesions and the presence of tumors or growths are the chief indications for pelvic surgery.

The relative importance and responsibility of each of these pathologic factors as a producer of distressing or dangerous conditions indicate to the pelvic surgeon the relative claim of each to surgical attention. Those of us who are convinced that no one of these factors should be neglected in any operation under any pretext, can not consistently endorse those surgical procedures, which include alone, the removal of pus or the pathologic specimen perhaps, but does not embrace the breaking up of all adhesions. We believe that the present growing tendency to do such incomplete work will be found unsatisfactory in time, as further study and experience reveal the evil consequences, remote and immediate, of such operations and render apparent the true origin of these consequences. Those who have a working as well as theoretic faith in complete work can not, to my mind, look with favor upon any vaginal operation for the relief of pelvic inflammation, the delayed operation for appendicitis, or the leaving of an abscess wall or gangrenous appendix, or bands of adhesions after opening an appendiceal abscess, nor upon the so called conservative work upon the appendages. Neither can they regard any peritonitis infected by an inflamed tube or appendix as ever cured except by operative measures. Illogic and misleading references to so-called clinical recoveries, the exaggerated advantages of a quick and easy operation, short time in bed, lessened shock and hidden scar will not, if they are true to their faith tempt them to subject their patients to the dangers of an incomplete operation.

In saying this I do not forget that among those who teach and practice these incomplete appendiceal and vaginal operations, and this so-called conservative abdominal surgery are operators whose skill, reputation and sincerity can not be questioned, and their honest belief that these methods give the maximum amount of relief, with the minimum amount of risk, is not to be shaken by ridicule, abuse, statistics or persuasive arguments. But I trust and believe that their conversion to the complete operation will come as the importance of peritoneal adhesions as a pathologic factor is made apparent to them in their practice.

The actual increased immediate risk of the complete operation, we can already approximately determine but the real point of contention, and that most difficult to make apparent and agree upon, is our estimate of the serious remote consequences of peritoneal adhesions, partially devitalized tissue remaining in the peritoneal cavity, pressure symptoms, etc. As further study, experience and observation shall reveal just how much and how little these factors have to do with our ultimate results, we will progress toward precision in diagnosis and in treatment In the meantime neither the diagnostician nor the operator can afford to be diverted by the urgency, prominence or immediate danger of other symptoms from a fair consideration of those less acute, more remote but not less grave, symptoms, complications, and sequelæ which usually exist and often menace the health, well-being and even threaten the life of patients suffering from pelvic disease

---

PELVIC INFLAMMATORY DISEASES

Presented to the Section on Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo, June 7 10 1898

BY A H CORDIER, M D

KANSAS CITY MO

This subject would seem to be worn threadbare, judging from its being so often used as a theme for discussion, yet the fabric, being of great surgical value, has rather improved by use and age The discussion of any topic in which the questions of human life and comfort are concerned is always timely and of interest

Sentiment and fashion should never be permitted to enter into a *proposition* where the question is one in which these unsurgical twins have long since proved themselves montrosities

Abdominal scars have been used as breastworks behind which some surgeons have hidden their fears of removing complications and the performance of complete work, while they made and abandoned tunnels in which the enemy threw up additional fortifications to repulse the invader who attempts to reduce their stronghold to liberate imprisoned organs and dislodge the offending cause

It is perfect surgery, or as near perfect surgery as possible that all surgeons should desire, but before accepting precepts involving human life and comfort, all evidence should be brought to bear on the topic, duly analyzed and weighed for its proper worth Occasionally a surgeon who has been obtaining almost uniform good results will give up the old for something new and uncertain

The limit and the character of the pathology should form an indication as to the character and the extent of the surgical procedure A succulent and pus infiltrated uterus, with possibly numerous pus foci surrounded with pus laden tubes and ovaries, should be removed, the choice of operative procedure being the one that, in the opinion of the surgeon, offers the greatest chances of immediate recovery from the operation, a permanent relief of the constitutional (septic) manifestations, the local symptoms resulting from the presence of these diseased structures, and the repairing of the damage to surrounding organs wrought by their presence

A cancerous uterus should always be removed, if seen before the disease has extended to surrounding organs The tubes and ovaries, as a rule, should be taken along with it, thus keeping as far beyond the diseased area as possible

A uterus known to be tuberculous should be removed along with the appendages, as by so doing a systemic infection may be averted The cancerous and tuberculous uterus, as a rule, can be removed through the vagina, for, if the disease has advanced so far as to involve the viscera, the case is an inoperable one and should be left alone so far as surgery is concerned The operation that promises nothing more than a specimen and a fee is not within the domain of legitimate surgery

In an old, recurring, puriform disease of the uterine adnexa, where adhesions are well organized and where the intestinal bladder and the omental attachments are firm, the vaginal method would be fraught with more danger than the abdominal These cases have established in part a peritonitic immunity by a prolonged and gradual process of auto-serotherapy, consequently the abdominal method is not so liable to inaugurate an acute, dangerous peritonitis or septicemia, as is often the case in the acute or primary attacks if operated on

Some of the advocates of the vaginal method, only a short time ago, maintained that it was an admission of incomplete operation to use drainage, yet they advance the good drainage by the vagina as an argument in favor of the vaginal route

It has long been an established and demonstrable fact, that in the majority of instances, the uterus is capable of taking care of itself, and that it does not give rise to any trouble by its presence after the diseased appendages have been removed I do not understand why an organ with a good and free natural drainage should not recover, and yet, as is claimed, an ovarian abscess or parts of diseased tubes, with walls as thick and as shaggy as a cocoanut, get well with an opening into the vagina

To remove the uterus and a part only (as is admitted in many cases) of a diseased tube and ovary, and leave a filthy sequestrum in the pelvis, and expect Nature to cure the case, is not good surgery, and a larger percentage will be found to have imperfect recoveries, fistulæ, and continuance of the pain, than if the work had been completed This it is possible to do, and it is done by good surgery when operating suprapubically

The Trendelenburg position and vision surgery took possession of the minds and technique of many operators a few years ago, and numerous articles were written lauding the advantages of that position while doing abdominal and pelvic surgery The pathology is really confined to the pelvis, but its effect and extension are often found at the umbilical level Some of the operators (and many of them are skilled and successful in every surgical sense) are now practicing and teaching the dark route (vaginal) method, where strong instruments, the sense of touch, much muscle, and adhesive or staying qualities are factors in the make-up of the surgeon and his surgical outfit, and essential to getting the specimen or part of it

The vaginal-route operation is not an easy one, neither is it as quickly performed as the suprapubic

Pus is not always found in the tubes and ovaries where their removal is demanded Firm and well-organized adhesions are often found binding the omentum, bladder, uterus, tubes and ovaries firmly together These adhesions were at one time Nature's breastworks thrown out for the protection of surrounding organs, but, like Nature's works in many other localities, she here fails to undo her imperfect work The vascularity or limit of these adhesions is only determined at the time of the operation An omental adhesion to the fundus may be torn across in the beginning of an operation, and scarcely a drop of blood escape, while in another, hemorrhage may quickly prove fatal A bleeding of this character is best controlled by a good ligature, such as it is only possible to apply in all cases correctly by the suprapubic method

A prolapsed uterus, surrounded by inflammatory diseased tubes and ovaries, can best be treated by a vaginal hysterectomy, removing appendages at the same time In this condition the uterus is not removed because of a fear that its infected state would preclude the possibility of a relief of the symptoms induced by the procidentia Some of these cases are cured by the removal of the appendages, a ventral fixation of the uterus, and a repair of the vaginal tears

Occasionally a gynecologist is called to see a case in the first attack, and finds the general state of the patient such that to attempt the major or curative operation would be fraught with a danger of such magnitude that it would be bad surgery to do otherwise than simply to make an incision into the mass in the vaginal vault and drain, with the idea of completing the operation at some future time All are agreed upon the course to pursue in such a case

If the case should prove to be a true pelvic abscess, one of those extremely rare cases in which the pus is extraperitoneal, or in other words, between the layers of the broad ligament, this seemingly minor procedure will be found, in the majority of instances, all that is necessary to effect a cure These cases are rarely met with in practice, and not so often in the literature of today as in that of former years To remove the uterus in such a case would be a sacrifice unwarrantable, as there is nothing to be removed but the pus

A failure to discriminate between this rare disease and the more common tubal disease, until in the midst of a vaginal hysterectomy, is extremely unfortunate, as it is then too late to retrace, while, if the incision was made suprapubically, the error would not be so expensive, and the correct course to pursue would be pointed out

It may be claimed that through a posterior vaginal opening the appendages can be examined, and the same deduction arrived at as though the abdomen was opened, but the fact must not be lost sight of that in these cases (true pelvic abscess) the pelvic peritoneum is clean and uninfected, and that a posterior opening endangers the safety of this structure A safe rule to apply here would be to cut into the bulging part where the pus is nearest to the mucous membrane

In the midst of a prolonged and difficult operation for the removal of the uterus and pus bearing tubes an alarming hemorrhage sets in, the exact source of which cannot be found The patient's abdomen is opened in the quickest possible time, with an imperfect asepsis, and the bleeding controlled, but three days later the patient dies from a peritonitis

The operator can not take the necessary time and precaution in preparing his instruments, his patient and himself, to do a clean abdominal operation, when the question of most importance is to quickly save his patient from hemorrhage The above remarks applicable to bleeding are of equal force in most instances where an intestine has been opened through the vagina Very few operators, I am sure would feel competent or able to put in a row of Lembert sutures, and make a closure of an intestinal rent that could be trusted to keep in liquid and gases

The mesentery, in cases where many adhesions are present, will be found thickened and shortened at the time of operation to such an extent that it would be impossible to pull a coil of bowel down into the vaginal opening, already filled with a dozen more or less, pressure forceps

In comparing the relative ease with which manipulation can be carried on through an abdominal incision and an opening in the vaginal vault, it must be remembered that the bony resistance met with by the impinging of the hand against the pubes is unyielding, differing very much from the pliant muscle of the abdomen under anesthesia

A small percentage of post-operative herniæ is found in following a large series of abdominal incisions, but these are discovered by the patient and not by the surgeon, and are not of such frequent occurrence as to be used as an argument against the suprapubic incision Time and close investigation of the vaginal cases will reveal an equal or a larger number of vaginal bowel protrusions

The length of the mesentery precludes, in most instances, the possibility of the intestine reaching the outer entrance to the vagina, and many vaginal intestinal herniæ will not be discovered by the surgeon owing to the return of the bowel when the patient is in the usual position for vaginal examinations In examining for a vaginal hernia, the examination should be made with the patient standing

It is not sound argument to advance that the woman with a vaginal operation can get up and be about in ten days, as it is not probable that the vault has healed so much more quickly than a smaller, clean, incised wound in the abdominal walls

One writer says "The abdominal scar is a source of great worriment especially to the French women, who are great admirers of a fair complexion and unblemished skin " A suprapubic scar and a low-necked dress may be incompatible in Paris Even some who held other views are made converts to this idea after visiting the French metropolis

Very few cases in abdominal surgery die from shock if the work of the operator is decisive and quick "Chronic surgery" and prolonged anesthesia kill many patients, regardless of the character or location of the pathology or route of surgical approach Septic patients endure anesthetics and slow surgery badly

One writer, and, by the way, a good operator, in praising the vaginal system, says "Landau has done good work, but in a great many cases he *opens the abdomen to finish* " (Italics mine) Landau is regarded as an expert surgeon yet in a large number of cases he is compelled in the midst of an already prolonged vaginal operation, to open the abdomen to finish his work, thus making two incisions instead of opening the pelvic and abdominal cavities This work can always be completed by the suprapubic route

Not a week ago, in breaking up universal adhesions, the appendix (which was diseased) pulled off at its cecal end, leaving a ragged opening in the cecum The discovery and closure of the bowel injury saved my patient Others have had similar experience-

A Florid Adage for a Dissecting room —The legend of the old Ohio Medical College dissecting room was as follows "Hic locus est ubi Mors gaudet succurrere vitæ" —this is the place where Death rejoices to aid life

SIGMOID SURGERY FROM THE INTRA-ABDOMINAL AND INTRAPELVIC STANDPOINT

Presented to the Section on Obstetrics and Diseases of Women, at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo , June 7-10, 1898

BY J G CARPENTER, M D
STANFORD KY

Diseases of the sigmoid have remained in practical obscurity, and the sigmoid per se, so far as the rectal specialist and general surgeon are concerned, have been a terra incognita November, 1885, the sigmoid cavity was first exposed with the light of research, and scientific truths observed in the living subject narrated and made a part of historic discovery by the writer The pathologist only knew diseases of the sigmoid as concerns malignant growths or benign neoplasms, or a possible sigmoid stricture, ulceration or fecal impaction, and what is now shown by Carpenter's sigmoidoscopy as a sigmoiditis with or without ulceration, was in the recent past supposed to be a proctitis or a colitis, the pathologist only dealing with diseases of the sigmoid as a postmortem observation Now, with sigmoidoscopy (Carpenter's) we are also able to not only explore the rectum in its entirety, illumine the sigmoid cavity, and with ocular inspection diagnosticate polypus or stricture of sigmoid, diminution of its lumen from encroachment of a tumor by pressure, or even a fecal impaction of sigmoid cavity, as well as the local inflammations peculiar to it It is surprising how little is known about sigmoidoscopy, or sigmoid surgery from the intra-abdominal standpoint Even our recent text-books in surgery, gynecology, and on diseases of the rectum and anus, do not mention sigmoidoscopy or sigmoid surgery from the intra-abdominal side, and he who advances must read the journals It is surprising how long it takes rectal and general surgeons to learn scientific truths about the anus and sigmoid when plainly told how to do so by the country doctor

Divulsion of the anus for disease is considered by general and rectal surgeons as a muscle operation, when in truth it is primarily a stretching of the nerves, and secondarily a muscle operation Rectal surgeons must learn that divulsion of the sphincters, besides its paretic and therapeutic effects on the lower end of the rectum and anus, causing rest, making the anus patulous and allaying irritability, curing pathologic lesions and doing massage, has another function, viz , nerve-stretching of the fourth sacral and inferior hemorrhoidal nerves, thereby cutting off connection between the spinal cord, the levator and sphincters, and placing at rest the bladder, rectum, vagina and perineum It is to be hoped that rectal surgeons will be able to see and learn this great truth and give the author due credit for the discovery The writer was informed about a year ago that a Louisville surgeon, in trying to illuminate the rectum and sigmoid cavity, punched a hole with what is called Kelly's sigmoidoscope into the sigmoid and entered the peritoneal cavity, and had to do immediate abdominal section to sew up the hole Had this surgeon used Carpenter's sigmoidoscopy, which is simplicity itself, full of reason and common sense, that hole would have never been punched He who knows how to do sigmoidoscopy does not need Kelly's superfluous and dangerous outfit, and he who has to use Kelly's ways should never attempt sigmoidoscopy

A prominent rectal specialist operated upon an aged gentleman about 60 or 65 years for internal hemorrhoids, and said, "Mr ———, you will be well in three weeks " At the end of this time the patient was a corpse from cancer of upper rectum and sigmoid aggravated by operation on the piles Had the rectal specialist used Carpenter's position and sigmoidoscopy before operation he would have been a wiser surgeon, and with more reputation, and not a sadder one now, and his prognosis would have been in keeping with his pathologic knowledge and true condition of his patient There is a vast difference between aseptic palliative surgery with bad prognosis, and complete life-saving surgery with favorable prognosis given, even in rectal surgery

Volvulus of the sigmoid is often difficult to diagnose, especially if patient has been battened with opium, and even now it is so common for practitioners to give opium to ease pain and conceal prominent surgical symptoms that otherwise would be highly indicative of surgical interference The symptoms of volvulus of sigmoid are former constipation, difficult to relieve, attended with distention and tenderness of abdomen or alternating with diarrhea, or following free purgation, severe exercise, indigestible food in large amounts, age of patient as a rule about 20 years, more often in the male than female, palpation may outline the volvulus, vomiting is often a prominent symptom, accumulation of fluid in abdominal cavity at a late stage of the strangulation, failure of bowels to act from purgatives or rectal enemata, or inflation with air, inspection with Carpenter's sigmoidoscopy Rectal enemata, even with patient in the Carpenter posture, will generally return if the hydrostatic pressure from the rectal side of volvulus does not distend and cure it By sounding, air inflation or hydrostatic pressure the sigmoid may become lacerated on its perineal side, torn, and leakage into peritoneal cavity result, with infection of the comma bacillus communi and other micro organisms and toxins, and rapidly produce septic peritonitis As delay and much taxis are highly unfavorable and dangerous to the welfare of patient, and the integrity of bowel in a strangulated hernia, so are palpation and rectal instrumentation with procrastination dangerous to life and integrity of bowel in volvulus of sigmoid With early prognosis, early diagnosis, quick, early life saving surgery, short anesthesia, with minimum of shock, under thorough asepsis, and before structural diseases have occurred, in skillful hands the patient's life ought to be saved

Diagnosis made of an intra-abdominal lesion demanding surgery Open abdomen in the median line if necessary, tap bowel with hollow needle or do enterotomy to let out gas or contents, with patient on left side, a short mesentery or intestinal adhesions, a constricting band or diverticulum or structural changes in bowel may greatly complicate withdrawal of the loops of intestine The bowel may not only be highly inflamed with linear tears of the serosa, but with gangrene at and beyond where the two flexures of bowel have been twisted on each other, and demand a section If bowel is healthy, return it to its normal position and stitch upper end of sigmoid to left side of abdomen, that portion of bowel opposite the mesentery, or as Senn states, shorten the mesentery, establishing a fold parallel to the axis of the gut If the flexure is gangrenous in spots, they must be resected, if gangrenous in its entirety, resect the whole flexure and unite bowel end to end by suture (Senn entero anastomosis, Murphy button, or do artificial anus) If the time is short, and anesthesia is making rapid inroads on the vitality of patient, do the latter operation, as it is attended with less shock, done with more haste and suits more cases, then later on do the radical operation

Stricture of the sigmoid from various causes demands similar life-saving surgery, according to the surgical demands and structural changes that have taken place in the bowel If a foreign body becomes lodged in the sigmoid and removal per anum is impossible, an abdominal section with enterotomy must be done for its removal

In malignant disease of the sigmoid we may be able to resect the growth, as Price, Senn, Bull and Hamilton have done, do an anastomosis or an artificial anus, the surgeon deciding on the condition of patient at time of operation and kind of intestinal surgery suited to each case, and his ability to do quick, life-saving surgery

That the sigmoid becomes seriously involved in intrapelvic disease, there is not an iota of doubt, that it has not been written upon by prominent gynecologists and authors of prominent text-books is surprising, to say the least Dr Joseph Price for years has demonstrated in his surgical clinics the lesions of the sigmoid, complicating surgical gynecology, and volumes might be written on surgical complications he has presented from time to time Those who know Dr Price best know he does pelvic and abdominal surgery without the Trendelenburg posture, but he has the *tactus eruditus* to a higher degree, and can see more with his fingers through a two-inch abdominal incision and discern more intrapelvic pathology than many surgeons can see with their eyes through a six or twelve inch incision and patient in the Trendelenburg position How common is it for the sigmoid to complicate tubal and ovarian disease The Fallopian tube, through leakage or infection in salpingitis, hemato- and hydro- and pyosalpinx, or ruptured tube in ectopic pregnancy, causes a local peritonitis of the left pelvis with a sigmoiditis serosa and adhesions to ovary, tube, uterus and bladder or an ovaritis per se may cause adhesion to the sigmoid and become imbedded in the broad ligament, the tube being in part or in total nested with the ovary and sigmoid, or there may exist an ovarian or broad ligament cyst fibroid or dermoid, and adherent to the sigmoid Again a pus-tube may be adherent to sigmoid on the left bladder in front, uterus to right, intestines above and broad ligament below, or an ovarian abscess, or multiple abscesses with pus-tube may complicate the sigmoid wall and the abscesses encapsulated in the pelvis by the sigmoid, bladder, uterus, broad ligament and intestines and omentum above, or these abscesses may from time to time, through pressure attenuation and maceration of the sigmoid wall, perforate the latter as well as the vagina, uterus, bladder, or peritoneal cavity, and leak or discharge and drain into the sigmoid cavity, and patient's life be saved by drainage and evacuation per sigmoid, rectum and anus How often in doing intrapelvic surgery do we find complications of sigmoid that is, by surgeons, especially Price s students, who have been taught to do thorough clean, life saving surgery and to deal surgically with surgical complications, as does Dr Joseph Price Often has the writer seen Dr Price curette the sigmoid wall, removing pyogenic débris down to the mucosa, healthy tissue, then repair this or these weak places by approximating serosa to serosa with the Lembert or continuous suture Again, he has seen this illustrious surgeon curette a sigmoid ulcer through a perforated sigmoid wall or excise necrotic spots with the longitudinal axis of the bowel and again repair the bowel with serosa to serosa, taking the Lembert stitch through the serosa and muscularis of sigmoid wall with the finest silk thread and needle The great reason why some abdominal surgeons have had great mortality following their work is that the needle and thread used to repair intestinal lesions has been too large, more like that of a darning-needle and thread Again, these surgeons have been afraid to hunt for and find sigmoid lacerations and other intestinal complications, and if found could not sew them Every physician who contemplates doing surgery should serve an apprenticeship in sewing with some good tailor or seamstress and have a skillful needle and scissors technic that comes only by practice, study and observation And every graduate should be examined specially on this, and the repair of gut lesions, before receiving his diploma The writer was raised on a large blue-grass plantation in Kentucky, and his mother used to make him take sewing and tailoring lessons when a young boy to keep him out of mischief and employed, so he was taught hemming, back-stitching, basting, darning, patching, tucking, quilting and embroidery, and his mother's sewing lessons taught him in childhood have been the greatest blessing to him in doing surgery The most delicate, refined and gentle sewing to be done is sewing the intestine for pathologic lesions and in plastic surgery one reason why intestinal suturing is so successful in skillful hands, viz , in inflammatory and traumatic lesions is, that if proper approximation of serosa to serosa is done, adhesive inflammation or agglutination of the serosa begins at once, and continues until definitive healing has been done in a few days then with fine needle and sutures there is no leakage Furthermore, the writer has been with Dr Price and seen excision or resection of sigmoid for stricture or malignant disease or benign neoplasm, and anastomosis with the Murphy button, or intestinal suturing or making an artificial anus when the strength of patient, the anesthesia, and the duration of operation would not permit of a surgical procedure of greater magnitude

The writer had the pleasure of seeing Prof Nicholas Senn do some of his wonderful surgery in entero-anastomosis and inguinal colotomy for malignant disease of rectum The best surgeons always try to do life-saving and not "*ideal surgery*," for the latter is *fatal surgery*, and should be done only in the dead house where the amateur surgeons should begin to operate It is a great thing to know just how much surgery the patient needs, how much can be borne with safety, and one had better do incomplete life saving and again operate at another time for complete life-saving surgery rather than do the "ideal and lose patient during or after operation The writer has seen the sigmoid ovary and tube, and appendix vermiformis adherent in one mass, the appendix stretching across the pelvis to sigmoid also the uterus retroverted upon the tubes and ovaries in Douglas pouch and sigmoid, bladder, tubes and ovaries internally adhered, so that it required the gentlest touch and manipulation and caution to find a point of cleavage and proper separation of the diseased organs without perforation Furthermore the essayist has seen in his own and Dr Price's of Philadelphia, uterine fibroids and dermoids attached intimately to the sigmoid as well as to the transverse and ascending colon and appendix vermiformis, omentum and mesentery, ovarian abscesses opening through the lower sigmoid and upper rectum with subsequent healing and contraction of the fistulous ulcers and scars has produced stricture of the bowel at these points The writer had the good fortune or misfortune to operate for appendicitis and organic stricture of sigmoid at the same anesthesia The sigmoid was extra long and the stricture relieved by the Murphy button anastomosis The appendix vermiformis was dilated size of thumb at its cecal end, inflamed and filled with soft feces and appendoliths, and required immediate appendisectomy

In conclusion, the essayist must state that all surgeons who do prompt, life saving surgery must camp upon the domains of pathology in abdomen and pelvis and do life-saving surgery, and will meet sigmoid and other intestinal adhesions that must be promptly separated, and there must of necessity be more or less serious intestinal lacerations that must be surgically repaired with as much precision, judgment and gentleness as a stab or gunshot wound of the stomach or intestine, and he who can skillfully and successfully repair these traumatisms will save more lives than he who does dashing surgery and neglects these intestinal lesions, trusting to nature To repair these lacerations it takes time, patience and perseverance, strong will-power and fortitude

The essayist cannot close without expressing the most sincere and profound thanks to Drs Price, Senn and Murphy for the valuable lessons learned through them in surgery and surgical pathology

THE TREATMENT OF SEPTIC PERITONITIS BY IRRIGATION

Presented in the Section of Obstetrics and Diseases of Women at the Annual Meeting of the American Medical Association, held at Denver, Colo June 7-10 1898

BY T J MAXWELL, M D
KEOKUK IOWA

Septic peritonitis has been, and is now, to the surgeon, the practitioner of general medicine, as well as the obstetrician, a "word of fear" Forty years ago we groped in darkness as to its cause, and now we are about as helpless in its presence as to a curative remedy, as when the fathers practiced blood-letting with a free hand and gave cathartics in heroic doses, or, on the other hand, administered opium to narcotism, keeping the patient in this condition until the disease exhausted the patient or the patient wore out the disease We are no longer in the dark as to the cause of septic peritonitis, and have made vast strides in the way of prevention, if not yet successful in the cure of the disease when fully formed We have adopted the consensus of opinion of the best informed pathologists, that practically all cases of peritonitis are caused by infection, though they do not deny the possibility of its idiopathic origin It is not possible today to state positively that exposure to cold, strains, and rheumatism never directly cause peritonitis, but that they do is very doubtful

Septic inflammation of the peritoneal sac is amenable to the general laws that govern septic infection of other tissue The progress and termination of inflammation in this tissue are modified by its structure and function We need but to remind you that the peritoneum is a shut sac lined with epithelium Underlying this membrane and connecting it with the lymphatic system are numerous lymphatic vessels, to the extent that it has been called a great lymph sac, with large capability for absorption, as well as possessing the function to secretion The large capacity to absorb is not surprising, when we take into account the extensive surface In all its parietal and visceral enfoldings it presents nearly as large a surface for absorption as the integument that covers the body The older pathologists and surgeons wrote over against this organ "*nole me tangere*" We know that this is a false accusation, in proof thereof we have not only the daily operation of surgeons, in which it is roughly handled, but the interesting experiments of Rinne, who has shown that the peritoneum will absorb large amounts of septic material if not subjected to injury, and those of Pawloki, in which non-pathogenic micro organisms and sterile foreign bodies were introduced into the peritoneal cavity without evil results Much depends, in all cases, on the general susceptibility of the individual to infection and on the vital resistance of the peritoneum itself Where the susceptibility is great and the resistance feeble, death follows, and where the opposite conditions exist life is saved

Another factor that plays a large part in determining the result is the character of the infection, and the culture media in which it may find a ready soil to grow "The characteristic of primary lesions is the development of hyperemia of the membrane, with formation of more or less copious glairy exudate, which, if it is in any quantity, rapidly becomes organized and produces adhesions," which bind the coils of intestines together, attaching them firmly to adjacent organs The character of this exudate varies greatly with the severity of the inflammation and its provoking causes While the plastic element is practically a constant factor in its make-up, its general character may be purely plastic, serous, or purulent, and in very infectious cases, sanious The purely plastic variety occurs in localized areas as a rule, and follows any simple aseptic injury to the peritoneum, in fact, is nature's response to injury, with the express purpose of repair It conserves the life by walling off and limiting the spread of septic inflammation, resulting in a circumscribed abscess, as seen in many cases of appendicitis It occurs after all surgical operations, and rapidly unites opposing peritoneal surfaces, covering up and encapsulating, as it were, intra-peritoneal sutures The infective bacteria or their ptomains have a peptonizing or solvent power over tissue So, in infective peritonitis, we have this plastic exudate changed, modified, liquified no longer endowed with adhesive power of gluing togething opposing surfaces On the other hand, the exudate may be largely serous, sanious or purulent, owing to the nature of the infecting microbes—whether they be pus producing or not

A purulent peritonitis is also very distinctly a septic peritonitis, but clinically and pathologically we are forced to recognize the fact that, either through a difference in vital resistance or in the virulence of infection, the same classes of micro organisms produce in one case what we call septic peritonitis, and in the other the purulent form

Inflammatory processes not only differ in their exudates, but present different morbid processes, for the septic peritonitis is invariably widespread, involving the entire peritoneum, while the purulent form is often localized through formation of fibrino-plastic exudate, which limits its spread It is probable, however, that these difference are in degree, not in kind, for, in those cases of septic peritonitis which live long enough, the exudate, which would have appeared serous had an early autopsy been made, is distinctly purulent and often putrid, this difference in degree depending, as we have said, on the severity and variety of infection and the individual resistance In this form we find not only a copious exudate which covers the viscera, but fluid in large amount in the abdomen in-which float layers of coagulated fibrin Should death occur in the first twenty-four hours of septic peritonitis, as it often does, no well marked changes are visible to the naked eye, save in some cases the duskiness of the peritoneum, and the presence of sanious, blood-stained serum in the dependent parts of the abdominal cavity

In all forms of peritonitis the walls of the alimentary canal in the parts become friable and edematous, while their peritoneal coat is readily detached from the muscular layers Whatever may be the cause of original disturbance, the pathologic process which results in the peritoneum may be divided into three varieties It may be localized and plastic, general and sero-plastic, or serous, changing to purulent

My object in this paper is not to dwell upon the etiology, pathologic anatomy or symptomatology—which is generally acknowledged and well understood by the profession at large—further than to serve the purpose of confirming the rational principles upon which I base the proposed treatment

There are certain cardinal principles well understood by the profession in the treatment of septic inflammation wherever found, viz If possible remove the focus of infection, or by free drainage and irrigation dilute and remove the toxic products This method is generally relied upon rather than the destruction of the pathogenic micro-organisms by germicides The profession seem to be slow in applying these principles in a radical way to diffused septic inflammation of the peritoneum Drainage and irrigation are practiced in circumscribed inflammations of the peritoneum with excellent results in many cases But this method often fails, the infection spreads to areas not drained, and soon the patient succumbs to septicemia If we could introduce some hot non-irritating fluid into this great lymph sac in such quantities as would reach every square inch of its convoluted foldings, so that it would seek out and dilute the lurking poison, and by a constant inflowing current and a corresponding outflowing current remove the poison it would fulfill the indications of rational treatment The normal salt solution fulfills all of these requirements The following clinical cases will illustrate its use and effects

Case 1 —Mrs N , aged 40, was being anesthetized preparatory to the removal of a double ovarian cyst , during the exciting stage of the anesthetic she struggled with great vigor, which produced a rupture of the left larger cyst. The contents of this cyst we estimated would measure one and a half gallons and it was of a brownish color and mucilaginous consistence that clung to the abdominal viscera with such pertinacity that it required gallons of warm salt solution poured into the abdomen, and the free use of the hands, before it could be removed so as not to be detected by the sense of touch The empty sac together with a smaller right ovarian cyst, was ligated and removed A large glass drainage tube was placed in position and kept free by means of suction as often as any fluid accumulated

There was but little, if any, shock, and not much nausea and vomiting from the anesthetic, for the twenty four hours following the operation, the temperature and pulse remaining nearly normal during the same period But at the end of thirty six hours, thirst and vomiting increased, pulse and temperature crept slowly but persistently upward, until at the end of forty-eight hours the temperature was 103 degrees F , pulse 130 thirst intolerable, and vomiting every few minutes a dark brown liquid, restless tossing in bed, with mental faculties wandering My patient was fast sinking from toxemia and I determined to try what thorough irrigation would do to save her I had several gallons of warm solution prepared The glass drainage tube was drawn up two or three inches and the irrigating tube introduced but the fluid would not enter the abdominal peritoneum until the wall of plastic limiting exudate was broken up, then the fluid flowed into the abdominal cavity, distending its walls Another tube was introduced alongside of the irrigating tube through the glass drainage, and the water was discharged through it , about four gallons of the hot (110 degrees F) salt solution was used in the first irrigation There was a marked change in the appearance of the patient at the close of the treatment the face lost its pinched and haggard appearance, the pulse fell from 130 to 212 per minute, temperature from 103 to 101, vomiting ceased, and the bowels moved freely within a few hours , thirst was allayed, and the patient expressed a desire for something to eat, hunger taking the place of nausea Irrigations were repeated every four to six hours, that is as often as the temperature and pulse began to rise Each irrigation promptly brought down the pulse and temperature These irrigations were kept up at lengthening intervals for four days, when the temperature and pulse remained normal

Case 2 —Miss M , aged 23, was brought to St Joseph's Hospital with a history of chill, followed by high temperature, irritable stomach, tenderness over lower abdomen, with gradual development of tumor in right iliac space This tumor suddenly disappeared, discharged without evacuation from vagina or bowels Pulse kept rapid, temperature 103 and upward Emaciation progressive In a few days the tumor began to rise or be manifest to palpation, and was six or seven inches in apparent diameter when brought to the hospital Her temperature was 102 to 103 degrees F , and pulse ranging from 120 to 130 per minute when she was operated on On opening the abdomen a tumor was presented, that was adherent to omentum, intestines and pelvic wall, whose cavity it completely occupied In attempting to separate the adhesions the tumor sac ruptured and a half gallon of very offensive smelling pus flowed , part mingling with the viscera, part externally The sac wall proved to be separated folds of the broad ligament The sac wall was emptied and stitched to the lower angle of the wound in abdomen and packed with gauze There were quite extensive adhesions of the bowls together and also to abdominal wall and omentum These I separated by introducing the hand into the abdomen, at the same time flushing the peritoneal cavity with liberal supplies of hot solution—temperature of solution about 110 degrees F —poured from a pitcher The coagulated lymph that coated the bowels was easily removed by slight friction and came away in flakes with the refluent current The temperature and pulse dropped very considerably, as observed soon after being put to bed Drainage of abdomen by glass tube was carried out as usual, by withdrawing the fluid accumulation every forty to fifty minutes Temperature and pulse began to rise in twenty four hours which was promptly controlled by free irrigation with hot salt water This treatment was repeated every few hours, as often as temperature showed tendency to rise or pulse to increase in frequency, each time promptly reducing both This treatment was kept up for four or five days, until there was no longer a tendency to rise of temperature or increased rapidity of pulse

There was in these two cases prompt reduction of temperature and pulse-rate each time the irrigation was repeated The salt water acted as it were by transfusion through the peritoneum, producing free liquid evacuation from the bowels Vomiting ceased immediately after first irrigation, thirst disappeared and the first patient expressed a desire for food within two hours after treatment Irrigation of the peritoneal cavity for septic inflammation or infection is in accord with the rational treatment of infection in other tissues, that is dilution of the infection and removal by free drainage Disinfection by germicides can scarcely be accomplished in any tissue We would not think of using a germicide in this great lymph sac The hot (110 degrees F) [illegible]ion irritant to either mucous or serous surfaces, it does not dissolve and remove the epithelial covering from either surface, as does pure water The heat stimulates the flagging heart and nerve centers The rapid transudation through the capillaries and lymph spaces of the bowel coats dilutes and flushes out the toxins already there This is demonstrated by the marked relief so promptly manifest in heart's action, temperature and cerebral function In order that this treatment be efficient it must be thorough, that is, the irrigation fluid must reach every part of the infected peritoneum This can only be accomplished by using large quantities, and where there is plastic exudate, sealing the surfaces together An opening in the abdominal parietes must be made sufficiently large to admit the hand, and with the fingers deftly separate the adherent parts, and with gentle friction detach the coating of coagulable lymph, for it is infected While this is being done a good stream of the irrigating fluid should be kept constantly circulating, so as to wash away the detached flakes of lymph, as well as the infected culture fluids and pyogenic cocci

The saline cathartic treatment of septic peritonitis, as practiced to a large extent by modern surgery is rational, and is successful in cases where the focus of infection is limited It sidetracks the toxins on their way to the general system But it fails in the prime indication to remove the center of production Irrigation does both If the focus of infection be in the sinuses of the uterus or its adnexa, removal is indicated, without hysterectomy irrigation of the peritoneum secures more perfect elimination by way of the mucous surfaces of the bowels than any other method

---

THE MEDICAL TREATMENT OF APPENDICITIS

Presented to the Section on Practice of Medicine at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10, 1898

BY ELMER LEE, A M, M D, Ph D
NEW YORK, N Y

There are no new truths, but there may be new phases of that which is old Progress means the development of new applications through invention and study Onward and upward is the direction in which the scientific world moves, and no one dares forestall the possibility of discovery in medicine that awaits the higher intelligence The bases of the unknown triumphs which will be the happy surprises for the future have their preparations in the knowledge and handiwork of the present The tools increase in delicacy, and number and become more and more adapted to the work of attaining the ideal of crafty man Methods of using old forces for pleasure or service in the arts and the sciences have greatly changed, and the evolution is for good The betterment is often a question for doubt by the pessimists, but judged from the standpoint of the universe, not by the little circle in which one mind operates, the roll of the years brings advantages to each succeeding generation which the preceding did not live to witness Everything moves toward some new standard or away from an old one Nowhere is the work of change more clearly revealed than in the duties and privileges of the practice of medicine Education teaches every man to think for himself, the printing press now puts that thought into imperishable tablets And what a monster tablet it would require to give a place to all that is said lately on the subject of appendicitis For one, my belief is that every new thought which is the honest opinion of the mind should be spoken, even if it be but a repetition

Who among physicians, then, is entitled to speak with authority upon disputed questions, for it is the experience of all of us that we claim the privilege today of correcting the errors of yesterday My plea is for an open mind in the consideration of medical practice Exclusive surgery desires to assume the responsibility for the treatment of the inflamed appendix, based upon the belief that it is only surgery which possesses the magic of cure Some physicians think that too much dependence is placed upon surgery, and that it is in many cases a dangerous intrusion without warrant These two classes are the extremes and it is well to understand the limitations of the question before us It is sometimes surgical, but more frequently medical, and as general practitioners it is desirable to examine the possibilities for good that are included in the medical treatment of appendicitis

The cause of appendicitis is seldom if ever exactly determinable, but as a rule, the health of a part depends upon the vigor of the general system When the symptoms of a localized disturbance in the intestine or appendix reach a point of sufficient importance to require medical counsel, the highest welfare of the patient calls for a conservative method of treatment which will prevent as far as possible the danger of subsequent complications and surgery A healthy body will not favor an appendicitis, while a safe and rapid return to health, if it is impaired, will either prevent visceral inflammation or be the wisest course in the cure General measures first and localized afterward, is a broad and effective plan of action in therapeutics

An immediate, but not the first, cause of appendicitis, is a partial or complete clogging of the circulation in the vessels of the appendix No satisfactory explanation known to the profession will cover every case The first determinable effect is congestion, closely followed by exudation of serum and lymph into the mucous and muscular tissues of the appendix and its environment The exudate stops both venous and lymphatic circulation, which is naturally followed by swelling of the mucosa and other structures of the organ Whatever particles of fecal matter happen to be within the canal of the appendix at the moment are either pressed out into the cecum, or they may be dammed off by a stricture and retained, and in consequence, undergo certain chemic changes The material may be crystallized by chemic action (the appendolith), or dissolved and reabsorbed, or discharged into the intestine if the swelling of the appendix subsides without destructive inflammation and rupture into intestine or peritoneum With what is happening, pain is likely to be a prominent symptom at the point affected, yet in some cases pain is absent But in any case there are enough symptoms from which to safely form a liberal and inclusive treatment of the patient, also broad enough to include the local part

It is probable that vasomotor control of the artery of the appendix and its branches is temporarily either depressed or exalted, and that there is for this reason too much blood or not enough in the affected part, each of which conditions could be the factor of danger in suitable cases Inflammation ensues upon congestion, destructive changes take place rapidly under the influence of an increase of heat and chemic decomposition of fluids and tissues, and at this stage the bacterial scavengers are present to help remove the retrograde products of inflammation The microbes are regarded as incidents of disease and pathologic change, and serve a further useful purpose in that their presence in excess occasionally confirms diagnosis They may confirm but not necessarily affirm diagnosis

The power to create as well as to cure disease resides in the body and never outside of it At this stage of appendicitis it is purely medical, and if always rightly treated it could not be surgical, save in certain and rare instances If neglected or improperly managed, secondary changes follow, such as ulceration, sloughing, necrosis and rupture, and even in these conditions spontaneous cure is possible and frequent But it must be admitted that in such cases the safer course is to employ the assistance of surgery

As soon as the physician suspects even that there is a possibility of appendicitis, upon first seeing his patient, the safe course is to be on the guard, and by this is meant to treat the patient, rather than the disease, with the view of preventing that which is suspected, or if too late for that, proceed in such manner as to actually give the best chances for a rapid recovery, and thereby provoke the least damage to the abdominal viscera

In all acute inflammatory diseases of the intestines my experience proves that food should be withheld from the patient for one, two, three or four days In cases where fever is a prominent symptom, the precise and life-saving course warrants the forbiddance of all food so long as the elevated temperature remains All alimentation, either by mouth or rectum, can be but partially digested and assimilated during the active stage of inflammation Even that amount of food which is capable of assimilation is in excess of the needs of the system at this stage of the case, and such nutriment as is not completely digested is a further increment of danger, together with other waste matter which forms the material for retrograde chemic action and autoinfection When food is needed a keen hunger will properly indicate it, and at such time moderate feeding is permissible, at regular and long intervals The hours for meals should be seven, twelve and six o'clock, as nearly as practicable Food too frequently given is a general mistake for which there is no justification The selection of food is important A diet of fresh vegetables and prepared sweet fruits stands highest in effectiveness, besides, it is better relished by the convalescent Good vegetables are procurable at every season of the year and in almost every locality, and always suitable The diet need not be exclusive, although a liquid one is freely advocated by some physicians as the best Nor is it strictly important that meat be omitted indeed the diet could be a mixed one if actual hunger is made the guide as to when the feeding should begin The main point is not to begin alimentation too early not to give too much or too frequently, and with particular instructions for most thorough mastication Casciani concludes from experimental studies that

1 In disease or during convalescence; a diet of fresh, well prepared vegetables diminishes urinary toxicity

2 Urinary toxicity is greater where the individual lives on a mixed diet and less where a vegetable diet is adopted

3 A meat diet increases urinary toxicity in direct relation to the quantity consumed

From the beginning of the treatment, six to eight ounces of fresh, pure water, administered with disciplinary regularity each half hour or each hour for the first, or first and second days of treatment, then if the case improves, let the intervals be two hours is a therapeutic resource of striking simplicity and exact scientific value The only valid counterindication is the use of discretion in disturbing the patient should he be asleep, none other exists to my knowledge Internal hydrotherapeutics are coming more and more to be accepted as the line of investigation upon which a sound basis of treatment is possible Recently the University of Heidelberg voted this branch of therapy into a full professorship, thereby recognizing the importance of less and less employment of drugs

It has been observed that a free use of pure water is an effectual laxative, obviating more drastic methods The laxative effect is aided by dissolving small pinches of common salt in draughts of hot water, given at the regular intervals Purgation is desirable, but when the intestine is undergoing active inflammation, harsh purgatives are seemingly useful, but actually harmful This is owing to the irritation excited in the mucous walls of the intestines, and also to the fact that the purgation is at the expense of the constituents of the blood

The hot saline or soapy enema will free the colon by quickly washing down the fecal contents The small intestines need no purging, for fermentation and decomposition are generally to be looked for in the ascending and meso-colon Such cleaning of the small intestine as may be useful will naturally follow upon the administration of hot water by the mouth, and from the effect of hydrostatic enteroclysis It requires two to three quarts of solution to ascend the colon and reach the cecum in an adult and one half the quantity in a child Irrigation is best given in the knee-chest position, though it is immaterial in what position the water enters the colon, so long as the quantity introduced is sufficient to partially distend the bowel all the way up to the cecum It may not be able to accomplish this satisfactorily in all patients, or perhaps not at the first trial But the water can be made to go to the cecum and do its bidding as far as the opening of the appendix, if used with a little patience and perseverence The colon, free of its contents, is an important beginning in the management of acute appendicitis as well as in other forms of enteric inflammation A short rectal tube, four to six inches long, of large caliber is the one now commonly used, the long tubes are no longer generally employed Water with pressure behind it will find its way more safely and naturally without the use of a special colon tube, which in practice may get no farther than the rectum or first fold of the sigmoid flexure

The oil treatment of appendicitis consists of the substitution of either sweet or olive oil for the plain or medicated water enemas and to some extent oil is administered by the mouth The results are said to be highly satisfactory which no doubt they are, though personally, my experience is limited to a few cases

It is possible and safe to use morphin and codein for the temporary relief of pain without impairing an inclusive diagnosis or the chances for rapid recovery provided the more important features of the treatment are faithfully and skillfully instituted and continuously maintained Of this there can be no doubt in acute cases seen at the beginning or at least early If the practitioner has not sufficient experience with practical hydrotherapy to feel like placing his whole confidence in it, a moderate administration of reputed internal antiseptics will do no great harm if the foregoing hydrotherapy is not neglected The advantages from prescribing the so-called internal and intestinal antiseptics are based upon belief and can not stand the test of unbiased experiment Dr Turck and others have sufficiently demonstrated the truth of this statement for all time to come

At the last German Congress of Internal Medicine, April 13, 1898, the addresses on "Intestinal Antisepsis" and "Autointoxication" proclaimed the paucity of our knowledge on this subject and the worthlessness of all antiseptics for this purpose They are only kept in vogue by the advertisements of the manufacturers Only one or two voices were raised in dissent to this timely and sweeping condemnation, which leaves only prompt evacuation of the contents of the stomach and intestines for our reliance in intestinal autointoxication The German profession has reached this sound conclusion rather late, but still in time to correct an abuse and thereby better serve their patients in the future

In severe cases of painful appendicitis cold water applied to the affected area of the abdomen is grateful to the patient and helpful in allaying both pain and excessive heat, consequently such applications aid in hastening restitution of the inflamed appendix My favorite compress is a small napkin saturated with ice water, frequently renewed, with a piece of flannel laid over it as a protective against wetting the bedding The ice coil and the ice bag, if not too weighty, are convenient and useful Gentle massage of the abdominal wall contiguous to the appendix is beneficial in cases where the inflammation is not of the fulminating character Sometimes a cold compress may be advantageously followed by one wrung out of hot water But where there is excess of local heat with fever, the cold works better, all things considered The hot poultices of flaxseed and other slimy material confer no important benefit upon the patient, their chief claim for usefulness depends upon an old tradition too sacred to be suspected by the unwise friends of the sick, and unfortunately the medical adviser himself even in some great centers of medical teaching indulges in this ancient but bad practice Where a hot poultice might benefit one of these cases ninety-nine cases would be injured The affected area needs no further heating, but on the contrary, the aim should be to arrest the inflammatory process by the cooling and tonic effect of cold water applications Tonic and stimulating aidance to the nervous system, often badly needed to arouse the bodily vigor and resistance, is assisted by brisk rubs along the spine by the hands dipped in cold water, or with a sponge cooled in ice water The effect is very frequently a magic influence for which nothing else in therapeutics can be a substitute The cold shower or spray would be still better if it were convenient, and the patient was disposed to submit, a thing not always to be secured, because of an unnatural fear instilled into the mind against cool water as a remedial agent Hot water used in the same way would act satisfactorily as a substitute if the objections against the cold water could not be overcome It is to be remembered that hot water is next in importance to cold in a therapeutic sense, and may in suitable cases be substituted for it

Bodily bathing in sickness is today almost uniformly employed, it is therefore but necessary to mention it If the fever runs high, the greater the importance of speedily lowering it by natural means, and the combined influence of internal and external usage of water in large quantities will more quickly and surely bring about a normal temperature, when safety and permanency are considered, than is possible with chemicals If there are those who would use the chemicals, let them not omit a full and thorough application of water therapy and its auxiliaries, such as good nursing, pure atmosphere, sunlight and sunshine freely admitted to the sick-room, together with that most urgent therapeutic measure of total abstinence from food during the first few days of the sickness

General massage has a place in the treatment of appendicitis, in that it supplies the physical exercise essential for the highest interests of circulation, respiration and digestion Ample resources are possessed by a body whose vigor is conserved during acute localized inflammations to check destructive tendencies and restore order In fatal cases it is the disordered state of the system that makes death imminent, and not the appendicitis, for the latter is a symptomatic expression of bodily sickness Ulceration, sloughing and even necrosis are not necessarily fatal in a body fortified with hydrotherapeutic management

Rupture sufficient to permit of the escape of fecal products into the peritoneum, according to Morris, would seldom happen if medical treatment from the inception was properly understood and directed The same author and operator further candidly affirms that medical treatment would save all but a few cases from the need of surgery, if medical practice was inclusive and scientific But if a choice is to be made between an up to date, skillful surgeon and an average physician, he decides that the chances of the patient would be better subserved by the former Under the aggressive teaching of modern surgery' many physicians are apt to lose courage in the attempt to control appendicitis, and it is not strange where the sole dependence is placed upon the healing effect of purgatives, opium, poultices and so-called intestinal antiseptics, and in those cases where that mistake of forced feeding at frequent intervals is permitted, together with other errors of medical management, it is quite natural that alarming symptoms should occur leading to a possible surgical crisis requiring an operation A rupture with escape of fecal filth into the peritoneum is not a pleasant thing, but it would rarely occur, according to the experience of one of the foremost surgeons, if the physician was capable of doing his whole duty properly and at the right moment

Large abscesses, wherever located, menace health and life, but there are conditions which make the presence of pus less dangerous than an operation would be in an unsuited condition of body In such cases the physician and surgeon wisely co-operate, thereby justly sharing the responsibility An abscess which is reasonably accessible in or through the abdominal wall, the same as elsewhere in the body, is easily opened and drained, but amputation of the appendix for a thickened mucosa or for almost any other reason save rupture, or where there is positive diagnostic certainty that rupture into the peritoneal cavity is imminent, frequently furnishes cases for the surgeon which still rightfully belong to the province of medicine

Chronic cases should come under a modified plan of treatment based upon the principles herein set forth, and kept within the control of the physician till all the symptoms are long since passed A healthy colon is the most important salutary factor in every form of appendicitis, for a clean colon is likely to be accompanied by a healthy appendix If there is a danger of appendicitis or if it has already occurred at some previous date, the successful way to prevent interval and other forms of appendicitis lies within the reach of such an one who happens to have a physician who comprehends, first, the value of regularly cleansing the colon once a week, by the hydrostatic injection of two to three quarts of blood-warm water The second great requirement for prevention of recurrence is moderate bodily exercise, performed with daily punctuality The third is moderation in eating The fourth is the habitual use of a sufficiency of pure water as a drink to satisfy the requirements of a body that is more than three-fourths fluid

There remains one point more, the experienced and really capable physician is entitled to a fee proportionately important to that which surgery expects, when the equivalent in service is rendered Medical treatment strives to save and prolong human life, and when the result to the patient is the same, whether through the assistance of surgeon or physician, why need the fee be widely different? The fee of $500 to $5,000 may or may not be too much for an appendectomy, but if the same end is safely and satisfactorily attained by the practitioner, why should his fee be less than that of his surgical contemporary? When the emoluments for medical work, skillfully and successfully accomplished, whether by surgeon or physician, are relatively similar, there will be an incentive for closer co-operation, higher medical thought and better treatment than prevails in some places at this time The practitioner is entitled to the full equivalent in exchange for intelligently performed services in the conservation of human life, and that equivalency should correspond to the measure of success in each case treated, with a proper and due regard for the skill, experience and years in medical practice

III DISCUSSION

Dr E A J **Rogers**, Denver—One has no idea how refreshing it is to one who has so long been in the dark to hear a physician offer, with such assurance and confidence that appendicitis can be treated medicinally with such results as he has stated I congratulate him upon the successful treatment he has given his patients in this disease From my standpoint I differ with him I am in doubt whether absolute medicinal treatment can be relied upon in appendicitis If any medicinal treatment is good, that which Dr Lee outlines is the best I have heard If men would follow more conservative lines many cases that now must be operated upon, sooner or later, would not have to be operated upon

I find myself diverging from Dr Lee in regard to the remarks made early in his paper his points in regard to etiology are different from those I was taught to believe in The primary cause of appendicitis I formerly believed to be a mechanical one The mucous membrane of the intestine is cleansed by an antiseptic fluid which is always present. Here may be found a little defect, and sometimes a little cul de sac, and here we find a stasis in the normal cleansing process Now, the organisms which Dr Lee has mentioned come in and play an important part Now then, the important point over which surgeons have been fighting comes in—what is the infection which causes the trouble? So soon as that can be determined, and we can state how the infection comes in, then we can lay down definite rules to guide us, then lay down rules as to what are medical cases, what surgical cases, and what cases are best to let alone Before this time, we are treating appendicitis in the dark

Yesterday afternoon, in the Section on Anatomy and Surgery, intense interest was given to the discussion which took place on the subject of appendicitis, this Section should have discussed this subject there in the surgical department and the whole topic studied together

A great point for us to consider is the nature of the infection So soon as this infection takes place, swarms of organisms begin their work of destruction If nature is able to master them, the disease is a trifling one, but if not, death may follow This point is an all important one, and it is the inability to determine this point that prevents us from forming the rules I just mentioned

Of course, there are surgeons who claim that this disease is absolutely and entirely a surgical one, but their arguments will not hold This disease should be treated by the physician and surgeon together If the surgeon is simply a mechanical one, then Dr Lee is right in not calling him in the beginning of a case, but a true surgeon is one who avoids the knife A true surgeon is one who knows how and when to use the knife If Dr Lee had a surgeon he could trust and rely upon, he should allow him to see the case in the beginning I do not believe that Dr Lee can tell in the beginning what course the disease is going to take, and it is only fair that a conscientious and careful surgeon should be called in the case from its very incipiency I must say in defense of the surgeon, if we trust him, call him early

Dr **Henry Sewall**, Denver—From personal knowledge on the subject I can agree heartily with what Dr Lee has said, particularly on the discussion between the physician and the surgeon I speak from the physician's standpoint You are called to see a case suffering from symptoms that suggest to you the idea of appendicitis, at least, it presents itself to you in a manner dependent upon subjective data If the observer believes pus has formed then no medical treatment, if the observer believes that inflammation is going on to pus formation then no medical treatment these are cases for the surgeon I suppose the common treatment of today is to eliminate functional disturbances which may give rise to symptoms There is no one here who has not found typic symptoms of appendicitis disappear like magic when the colon was thoroughly emptied, but, if the symptoms are not relieved, then the case calls for the exercise of judgment It seems to me that the average physician should take a place mid way between those who urge that every case of appendicitis should be operated upon and those who do not operate upon their patients until almost the time of death I will only say this, that suppose you let a case of appendicitis go on to recovery—so called—under medical treatment the treatment the reader of the paper suggests in the body of his work, you expose the patient to certain dangers Not long since I had under observation a patient who had multiple abscesses of the liver, at the autopsy there was found a cecal abscess The man disclaimed ever having had symptoms pointing to appendicitis I believe these cases are quite common, in my experience I have seen four or five of such cases I can not help but think that cases of appendicitis are to be regarded as cases that belong to sanitorium care

Dr **Herrick**—I have heard the question discussed ably and well from different standpoints, this question was discussed in the surgical Section at great length The physician and the surgeon are antagonistic in the consideration of this subject, the former dealing with certain phenomena and the surgeon dealing with the facts I make a point that the physician has different ground to stand upon than the surgeon

The question has arisen as to the cause of the disease Are not all processes of digestion due to the secretions? The intestines and their attendant glands are of the first importance and consequence If that is so we may well look to the condition of the secretions As a matter of fact we generally find in appendicitis disturbances of the secretory organs Disturbances of the liver and other disturbances cause changes in the whole portal system disturbances of the natural secre tion cause a disturbance of the colon As a result of irritation we have congestion of the veins of the mesentery, presently we find a cause in the distension of the colon from the impairment of circulation and secretion a subacute inflammation follows An impaction of the intestine with fecal matter is then noted It is this condition of impaction of the colon with arrested secretion that, in all probability, is the cause of appendicitis, at least, it seems to me to be so Let us not cut off the appendix, let us not give up the idea that we can relieve these patients Treatment by diet is successful I have practiced medicine thirty seven years, and I rarely lose a case of appendicitis In the last ten or twelve years I have lost but four cases As to the treatment, one generally applies ice bags Do not give opium or anodynes

Dr Baily, Kentucky—I am a little skeptical about Dr Lee's promising as much as he claims by the methods mentioned What has he done in this line? How many cases of appendicitis has he treated by the methods mentioned, and with what success? As a general practitioner, I am bound to say that the diagnosis at the very beginning is the most difficult one to make, and it is at a time when it is most important that we should make it Realizing the responsibility, I am most willing, as early as I suspect the disease, to call in an intelligent surgeon, I have never called one in where I have had reason to regret it In the majority of cases the general practitioner should have a consultation with a skilled surgeon Many of these cases get well without treatment, but the surgeon who can do the operation without mortality ought to give the patient a chance for his life

Dr Tyson, Philadelphia—I have but a few words to say, and in confirmation of what Dr Baily has already said I believe that cases of appendicitis are difficult of diagnosis My experiences lead me to believe that many cases of supposed appendicitis that get well under medical treatment were not cases of appendicitis at all In cases of appendicitis I want a skilled and competent surgeon, not for operating, but for his judgment. I have had surgeons who have had more experience than I have had, their judgment will help me If I am satisfied that appendicitis exists, I am willing the appendix should be removed

Dr Walker, Philadelphia A gentleman, who lived in Philadelphia was seized with appendicitis, I attended him through the attack and at no time did the surgeon or I think that an operation was desirable The gentleman desired to leave the city, and he was advised, therefore, as there might be a recurrence of the attack, that it would be better for him to have an operation performed The patient was perfectly well, and rode much about the adjacent country, on the street cars, etc, with no temperature or any evidences of trouble A day was fixed for the operation At the time of operating, there was found one pint of pus back of the colon, this had given no evidence of its presence or pointed toward any danger to life To me this was a very interesting case, I thought the patient was cured of his appendicitis, but he was not. The appendix was swollen and perforated

During the succeeding year I saw a case that no one would admit the necessity of operating upon He passed through the attack, later, the surgeon again saw him He was examined, but there was no evidence of disease whatever This year, in May, he was taken with symptoms of typhoid fever I happened to be present in the doctor's office when he mentioned the unpleasant symptoms The doctor prescribed for him, and he was treated three weeks for typhoid fever I reminded him of the previous attacks of appendicitis, and I thought of a pus collection somewhere A pus sac was found, and the patient is now perfectly well The pus had been lying there from June to May This has been a lesson of value to me Although I believe that the majority of cases are cured by medicinal treatment, still we can not be too careful

Dr James, of Missouri—I have been led to believe that appendicitis was a disease that belonged exclusively to the surgeon, and that the general practitioner had no right to claim any knowledge of the disease Public sentiment demanded that the cases be all turned over to the surgeon

Water is of great value in the treatment of this disease both internally and externally, I also like it used per rectum I have used the cold applications as described by Dr Lee and I use it especially if there be high temperature But, I prefer the hot applications, because, as a rule, the temperature is rarely above 102 F I have overcome the demand for anodynes I instruct the nurse to keep up the hot applications even at the expense of rest

Dr H A West, Galveston, Texas—I can not conceive any more important subject in medicine than this I array myself on the side of many here in combatting the idea that any antagonism between physicians and surgeons exists as mentioned The responsibility of the physician arises from the fact that he is usually the first to see these cases they come to him in the first place The man that assumes the responsibility to himself of treating these cases as medical ones and imagines antagonism as mentioned is assuming a serious responsibility His first thought should be the care and cure of his patient So far as medical treatment is concerned, cases that get well recover by themselves Medical treatment amounts to extremely little As Dr Tyson has said, when the diagnosis of appendicitis has been made, I want the advice of an able and experienced surgeon, I want one who has had the opportunity to see many of such cases It seems to me that it is the physician's duty to call to his aid a surgeon I have seen a patient with a normal temperature and pulse and who was feeling perfectly well, yet a perforated appendix was found, nothing short of an operation would have saved that case Water given internally, externally or eternally would not have saved such a case

Dr C F Ahrer, Fort Madison, Iowa—I desire to say that we are all more or less influenced by our prejudices or peculiar trends Many men who have a surgical trend or prejudice naturally desire that all diseases may become surgical, and must so be treated, and men who have a medical trend wish to cure everything with pills and powders In some cases both these men are wrong The attitude of surgeons toward physicians in smaller cities and country districts, when the struggle for existence is the prime factor is not as charitable as it should be, and when we remember, though we are all good fellows, that in many men the hog principle is not yet all rooted out, this attitude coupled with the trend to cut often works infinite mischief to the physician and to his patient. Again, in these districts outside the large surgical centers where honest and competent surgeons can be had without the drawbacks above mentioned the population are not trained to accept surgical interference when needed In places where good surgeons are not to be had, if I had appendicitis I would rather trust a good physician than a bungling incompetent surgeon, for in the former case I might recover, in the latter I must surely die Were we less fallible and more honorable than we are, we would always do the proper thing, but until then we shall have the same troubles which now beset us So in appendicitis, as well as in other diseases, we are often controlled by circumstances, and under such circumstances we can do only what we honestly and conscientiously believe to be right If we do this our patients have little to fear

Dr Elmer Lee, New York—I recommend the reading of the paper at your homes, because the answers to the questions raised by the gentlemen who have spoken will be found there I stand before you to plead for the lives of the patients, and in so doing it is my experience after seventeen years of medical practice, that many lives are in jeopardy through the mistakes of the doctor or of the surgeon or of both I am not an exclusive I believe the methodical work of the physician is to be considered foremost because he is the one to see the patients first If the physician did his whole duty in the incipiency of the case few cases would go to the surgeon Recently a child, in Boston, was taken sick with pain in the abdomen The doctor administered opium in the night The next day the doctor came again and gave a purge The next day he came and continued the treatment The next day he came and the child was considerably worse for the treatment A surgeon was called—about four or five days after the beginning—and an operation was decided to be necessary The child was operated upon and died He had been a healthy vigorous boy, but he ate too much candy and food and took but little exercise The condition which produced the fatal termination I am sure could have been cured by the intelligent application of the lines laid down in the paper When I find that I am mistaken in my views I will be happy to come to you and acknowledge my mistakes The physician does not stand equal with the surgeon in these modern days, and a stigma rests upon the medical profession I am trying to overcome it, and it seems to me it can be overcome It appears to me that it is within the range of medical treatment to manage the vast majority of inflammations of the abdominal viscera

I have not paid much attention to statistics I plead derelict in coming before you without mechanical statistics I do not know much about them If patients do not die that is all sufficient for me I can not tell if perityphlitis, appendicitis or colitis exists, it is impossible for a physician to verify what was a diagnosis of appendicitis, that is only possible for the surgeon who has a mechanical result, it can not be done in medicine It is only my opinion that those cases treated by me have been cases of appendicitis, it may involve the colon or the cecum I do not know how to make an absolute diagnosis, it may be done in this country and in Europe

COLPOPERINEORRHAPHY AND THE STRUCTURES INVOLVED

DEDICATED TO DR THOMAS ADDIS EMMET AND MR LAWSON TAIT IN RECOGNITION OF THEIR LABORS IN THE SURGERY OF THE PERINEUM

BY BYRON ROBINSON, B S, M D
Professor in the Chicago Post Graduate School of Gynecology and Abdominal Surgery, Professor of Gynecology and Abdominal Surgery in Illinois Medical College Professor of Gynecology and Abdominal Surgery in Harvey Medical College Gynecologist to St Anthony's Hospital Consulting Surgeon to the Mary Thompson Hospital for Women and Children
CHICAGO ILL

The structures involved in the repair of a defective perineum are muscles and fasciæ The operative procedure consists in denudation with coaptation or flap-splitting methods Notwithstanding the successful claims in the varied surgical methods of colpoperineorrhaphy the anatomical basis is neither generally nor perfectly understood It is probable, however, that the essential success lies in the reunion of the separated levator ani muscle by means of its fasciæ superior and inferior with some other fasciæ, and also that this success has been chiefly due to deep suturing The object of this essay is to demonstrate that the chief factor in successful colpoperineorrhaphy is the restoration by the aid of deep sutures of the fasciæ, especially the levator ani fasciæ, superior and inferior

The muscles of the pelvic floor may be divided into two classes *a*, the deep layer—the levator ani coccygeus and pyriformis, *b*, the superficial layer—the transverse perinei, bulbo cavernosus and sphincter ani externus A peculiar characteristic of the muscles of the pelvic floor, and one which demands respect in colpoperineorrhaphy, is the extensive fascial attachments of one or both ends of the muscles The levator ani, the bulbo cavernsous and the transversus perinei have a fascial attachment We will consider in detail the muscles and fasciæ involved in colpoperineorrhaphy The basis of this labor is a careful anatomic investigation with considerable clinic and surgical experience

THE LEVATOR ANI MUSCLE

The levator ani muscle is perhaps the most difficult to understand as regards its form, insertion and function The origin of the muscle is sufficiently plain and is considered established by anatomists Few agree as to exact insertion, even at this late day, and opinions vary as to the exact function, form and insertion of this muscle, My own investigations demonstrate that there is a foundation for these varied opinions

1 The insertion and origin of the levator ani vary as to the extent of distinct muscular loops which embrace the rectum and vagina, as to the tendinous raphæ (between muscle loops and distal ends of the coccyx), also regarding the precise relation to the vaginal wall, whether muscular or connective tissue, and also as regards the exact relations to the muscle of the lower end of the rectal wall Moreover, its partial fascial origin and insertion is sure to endow the extremities with varying appearances as to the length of the fascial or tendinous conditions in other words the distance of the red muscular fibers from the extreme origin and insertion of the levator ani vary Perhaps this variation in insertion may be explained by considering the levator ani as a rudimentary muscle and to be disappearing with the tail Its double fascial accompaniments complicate its origin and insertion as well as the interpretation of its function

2 The various opinions as to the form of the levator ani are explained by differences as regards sex idiosyncrasies of individuals, disturbances from gestation and parturition, variation of the shape of the pelvis and fascial insertions and attachments

3 The different views as to the function of the levator ani lie in confusing its function with the levator ani fascia, superior and inferior, in exaggerating its size and attributing to it function and utility belonging to other genital supports It is especially erroneously inferred that a muscle will act as a continuous tensionized support for any viscus The knowledge of the levator ani muscle is fragmentary and difficult of access Its dissection is far from easy and its adjacent relations are complicated The muscle does not resemble a funnel with the rectum or vagina at the bottom or apex, but is more similar to a sling, a flat loop or a horseshoe, which does not pull the rectum or vagina directly upward, but draws the two canals forward and upward toward the pubic cord

The muscular loop of the levator ani muscle resembles a horse's collar encircling the rectum or the vagina In the female it vigorously controls two canals—rectum and vagina—yet its control of the vagina depends on that of the rectum The rectum being forced forward against the middle of the posterior vaginal wall produces the H-shape to the vagina The excess of vaginal wall is compelled to fold at the sides producing the upright columns of the H It is very thin In an excellent specimen which I dissected from a good sized woman the levator ani muscle is so thin as to be really membranous, and the muscular band between the vagina and rectum is but a few lines in thicknes It is really a pelvic diaphragm The muscle should be considered as to its origin, course and insertion

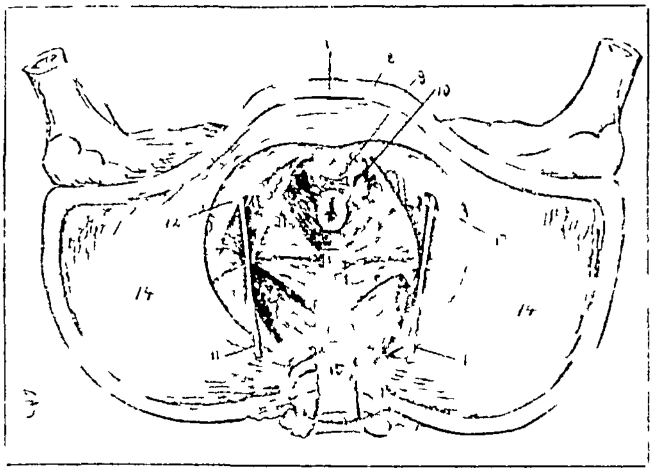

Fig 1 —(Robinson Scholer) This cut is drawn from a female pelvis dissected by the author and intended to show the muscular floor of the pelvis with fascia dissected off 1, 1 the levator ani muscle 2 2 the white line or origin of the levator ani 3 3 the obturator internus muscle 4 4 the coccygeus muscle 5 5 the pyriformis muscle 6 6 the inner wall of pelvis 7 7 sacrum H H the horse shoe loop of the levator ani muscle drawn darker 8 the Y shaped urethra 9 the vagina cut close to the pelvic floor whose wall does not flare like the radial wall 10 11 11 the obturator nerves 12 12 inner wall of pelvis 13 pubic crest 14 14 iliac fossa 15 last (5th) lumbar vertebra

Origin —The levator ani muscle arises from bone from the posterior surface of the pubis and ischial spine or from fascia, arcus tendineus and vesico pubic ligament The bony origin is the posterior surface of the pubic bone and ischial spine The larger portion of the levator ani of bony origin arifrom the posterior surface of the pubis It begins about half an inch from the symphysis and one and one-half to two inches below the pubic crest This point of origin is about two fingers wide or one and one-half inches, and does not meet its fellow of the opposite side, one-half to one inch existing between them on the posterior surface of the pubis, which is filled in by the obturator fascia The bundle of muscles originating on the posterior surface of the pubis passes downward and backward to embrace the vagina and rectum This is the pubic sling or horseshoe loop, which is quite thick and strong in some cases, and very thin and membranous in others The margin of the loop which is applied against the sides of the vagina and rectum, is often the thickest part of the muscle The muscular bundles of the horseshoe loop join those of the opposite side of the levator ani posterior to the vagina and rectum without an intervening perineal tendon or raphe In some dissections it is absolutely plain that no tendinous raphe exists, while in others it can not be told

The smaller portion of the levator ani of bony origin is from the ischial spine immediately anterior to the origin of the coccygeus muscle Quite a distinct strip one-fourth to one half inch wide comes from the ischial spine, and can be plainly followed by the eye to the horseshoe loop

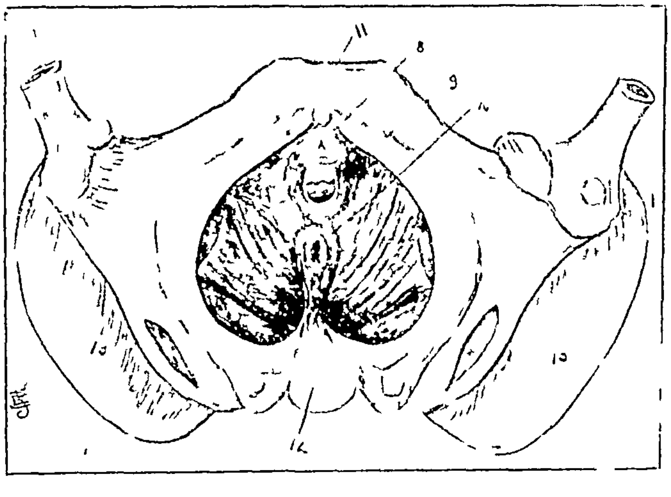

FIG 2 —(Robinson Scholer) This is a cut drawn from a female pelvis dissected by the author It illustrates the inferior surface of the pelvic floor On the left side (in the fig) the levator ani fascia inferior is not dissected off while it is on the right side showing the inferior surface of the levator ani muscle 1 1, shows the levator ani muscle with its parallel bundles 2, *the levator ani fascia inferior*, 3 3 *the obturator internus* muscle, 4, 4 the coccygeus muscle 5, 5 the gluterus maximus 6 ano coccygeal structure, 7 7, the horse shoe loop of the levator ani showing some muscular bundles coursing between rectum and vagina It is not so large on the inferior surface as it is on the superior surface of the pelvic floor 8, urethra 9 *vagina*, 10 *anus flaring* 11 pubic arch 12, sacrum 13, flaring ilium

The ligamentous origin is from the anterior ligament of the bladder (ligamentum pubo-vesicale) and from the arcus tendineus (white line) The fibers of the levator ani which arise from the ligamentum pubo vesicale are of little practical importance The white line extends in a slightly curved direction from the posterior lateral surface of the pubis, over the obturator foramen to the spine of the ischium The anterior end lies two and three fourths inches below the ileo-pectineal line, with a length of about four inches The white line (arcus tendineus) is a part or an extension of the anterior true ligament of the bladder, a thickening of the levator ani fascia superior In the white line, the muscular fibers arise as fine tendinous bands, and may show their reddish muscular nature at the white line or a short distance from it The muscle may shade into a flat tendinous layer before it reaches the white line The proximal tendon of the levator ani muscle varies much as to its relations with the white line It may arise below it as well as from it The white line may project into the pelvis as a tendinous fold, and be capable of being separated from the origin of the muscle

The course of the fibers of the horseshoe loop of the levator ani muscle is backward and downward in two fleshy bundles, the smaller to the side and posterior surface of the vagina, and the larger to the side and posterior wall of the rectum The loops which pass along the sides of the vagina seem to be attached to the vaginal walls by connective tissue only, while the loops of muscular fibers which embrace the rectum interweave with the muscular bundles of the rectal wall, forming a strong connection The part interwoven in the rectal wall acts as an elevator It would appear that in some cases the loops of the levator ani interweave with the muscular fibers in the wall of the vagina The part of the levator ani which passes between the vagina and rectum, is a small, thin band, one-sixth to one eighth of an inch in width, which arises from the external part of the pubic origin and passes over the large belly of the muscle to gain their rectovaginal situation Its relations to the wall of the vagina are very close if not interwoven with its fibers

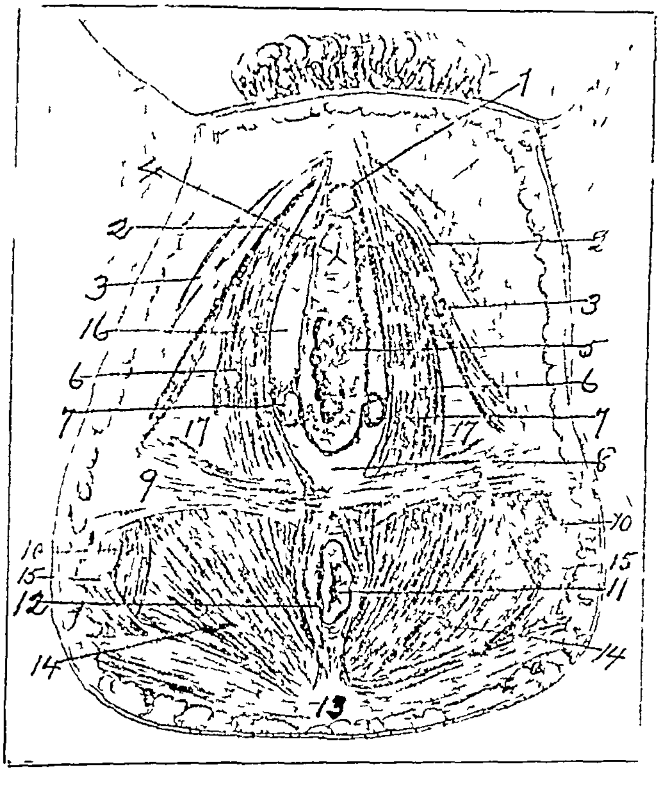

FIG 3 —(Author) This figure I drew semi diagramatically to illustrate the general view of the pelvic outlet 1 clitoris, 2 crura clitoridis 3 erecto clitoridis muscle 4 urethra 5 orifice of vagina 6 bulbo-cavernosus muscle 7, vulvo vaginal glands (of Duverny, of Barthalin of Tiedeman) 8, *posterior vaginal commissure* 9, transversus perinei muscles 10, obturator internus muscle, 11 anus 12 sphincter ani externus 13 coccyx 14 levator ani muscle 15 great sacrosciatic ligament 16 the bulb of the vagina 17, deep layer of superficial perineal fascia

The part of the muscle of fascial origin which arises from the white line, passes backward and downward, becoming part of the levator loop and partly inserted in the tendinous perineal raphe and the last bone of the coccyx Many of these fibers pass downward in a curve and when near the median raphe they turn acutely backward to become inserted into the coccyx A few of the muscular fibers arising from the white line, as well as from the horseshoe-shaped loop together with some from the ischial spine, embrace the rectum The part of the levator ani arising from the ischial spine becomes inserted chiefly in the coccyx Yet one may observe one fourth of an inch in width pass around the rectum with no intervening tendinous raphe

The part of the levator ani muscle of special interest to the gynecologist is the two-fingers wide, horseshoe-shaped sling which arises from the posterior surface of the pubis and passes backward and downward to embrace both rectum and vagina It is the belly of this loop which gives the rectum its forward curve just before the anal end is turned backward It is the sphincter portion of the muscle It is this part of the muscle which becomes hypertrophied in vaginismus It is the portion of the muscle torn and separated in lacerated perineum It is the portion of the muscle which retards labor, creates vaginal spasms and may prevent coition and in rare cases prevents the penis from escaping until relaxed by an anesthetic In most cases the levator ani behind the rectum may be divided into three quite distinct parts viz *a*, the part which is connected to the last bone and fascia of the coccyx The fibers accompanying this portion of the muscle originate chiefly from the posterior end of the white line or at the ischial spine *b* A portion of the muscle forms a median tendinous raphe for about one third of an inch immediately in front of the coccyx *c* The portion of the muscle immediately behind the anus about three fourths of an inch wide has no intervening tendinous raphe (not always distinct) and consists of the belly of the loops which originate and insert on the posterior pubic surface In other words, the muscular fibers of each side anastamose forming the horseshoe shaped loop with no intervening tendinous raphe Some of the loops intertwine with those of the sphincter ani which pass back to the tip of the coccyx also some of the muscular fibers of the sphincter ani externus are continuous with the loops of the levator ani The fibers of the levator ani originating from the white line pass backward and downward but on arriving at the median raphe many of the fibers turn sharply backward to be inserted into the coccyx, and soon become tendinous The levator ani fascia superior is not very intimately attached to the muscle, and may be compared to the fascia transversalis The levator ani fascia inferor is adherent to the muscle

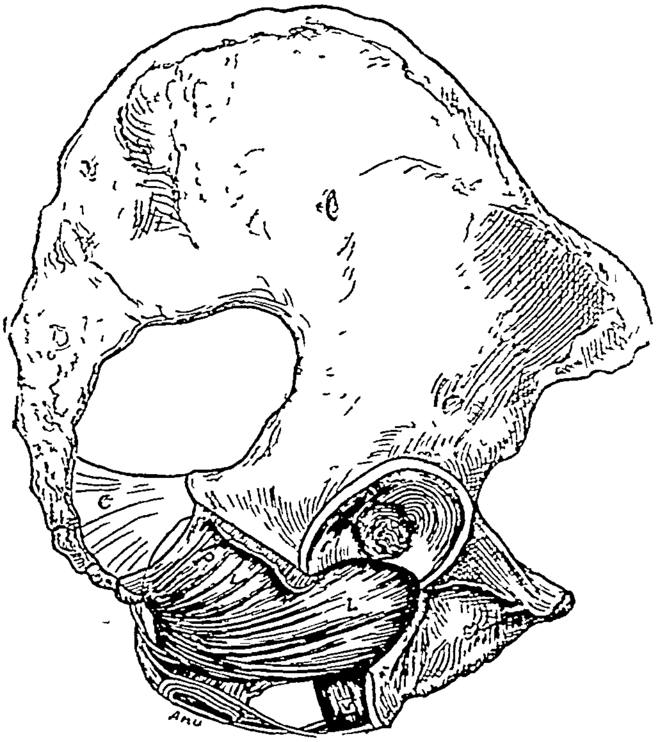

Fig 4 —(Luschka 1864) Redrawn and modified represents a view of the levator ani muscle L L the modification of Luschka's figure consists in magnifying the rectal curve made by the levator ani muscle C a continuation of the levator ani muscle backward drawn lightly V vagina? The grip on the rectum by the horse-shoe sling of the levator is here plain p The levator ani fascia inferior p is shown rolled up

Deductions in regard to the levator ani muscle may be numerous Certain practical considerations may be drawn from a careful study by dissection and in gynecologic practice As it was originally a muscle of the tail it is becoming vestigeal in man, shown by its fascial connections From the origin, course and insertion of the levator ani muscle, it must be viewed as the all-important muscle of the pelvic floor

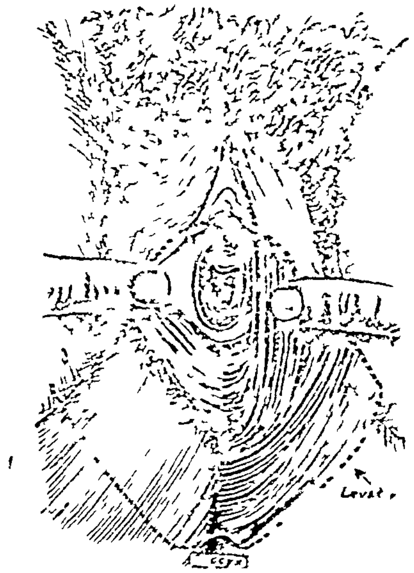

Fig 5 —(Dickinson 1889) The levator ani as seen through the skin the outlet of the pelvis is dotted and the direction and course of the chief muscular bundles of the levator ani marked out

The levator ani fascia superior is the real visceral support I think it was Dr Meyers a German physician, who first happily named it the pelvic diaphragm In many subjects it is membranous The normal muscle has the shape of a boat, and when this boat shape becomes cone-shaped the pelvic floor is impaired The levator ani is composed of many muscular bundles coursing chiefly parallel to each other but also at varying distances The bundles are flat ribbon-like, and of a bright red color The bundles of muscular fibers are held at greater or less distance from one another by collections of fat or connective tissue in varying degrees Fenestra or apertures are commonly observed between the muscular loops The capacity of the bundles of the levator ani muscle to separate and reunite without injury serves a useful purpose in labor when rapid and wide distension of the pelvic floor may occur Too many figures illustrate the muscle as a distinct plane with no parallel gaps between the bundles

The levator ani (the deep muscular layer of the pelvis) is connected to the external sphincter ani of the rectum and vagina (the superficial muscular layer of the pelvis) and by this muscular connection to the perineal body (the punctum fixum), the deep and superficial muscular layers of the pelvis are brought into intimate relations of much utility A few fibers are lost in the perineal body The levator ani is in closer organic relation with the rectum than the vagina, because the rectum requires more frequent and perfect evacuations than the vagina It is chiefly a sphincter muscle The weakness of its origin, insertion and direction of its fibers is in accordance with its fading out of existence

The forward curve of the rectum is due to the horseshoe shaped loop of the levator ani, which originates chiefly from the posterior surface of the pubis By the contraction of the lower, stronger fibers of the levator, the lower portion of the rectum is forced against the perineal body, which compels the anus to turn backward and to evacuate its contents

The levator ani, on account of its shape and size leaves deficiencies in the pelvic floor, which are filled in front by the bulbo cavernosus and behind by the coccygeus muscles, its continuation backward

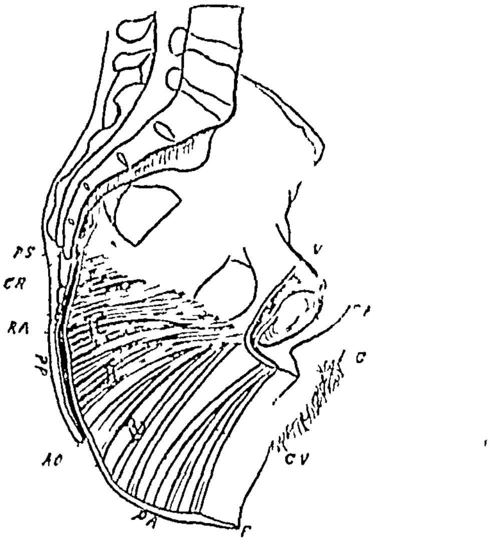

Fig 6—(Varnier, after Dickinson) The distended levator ani V bladder, S P, symphysis c, clitoris C, V constrictor of the vulva F, fourchette P, A, anterior perineum, A O anus P, P posterior perineum, C, R, coccyx P S point of sacrum, R, R R, is on the muscle with its separated bundles the middle R is on the strongest bundle In this figure we observe how the muscle can save itself from rupture by the separation of its various fasciculi It yields better than if it were in one connected sheath

The palpable rounded edge of the levator ani lies three-quarters of an inch above the anus and three-quarters of an inch above the vaginal opening, making the muscle, in fact, a regulator of the external openings of these two canals Normally the orifices of the canals are always closed They remain open only by internal or external force or from trauma

The levator ani will lift from five to twenty pounds, averaging about ten as noted by Dickinson Its strength soon tires out assistants in vaginal hysterectomy From its insertion into the perineal body the external sphincter, post-rectal raphe and coccyx, it draws forward the post-vaginal structures of the pelvic floor In the excellent work of Savage, he names the portion, from the principal bony origin, pubo coccygeus This is erroneous, as these loops do not pass as far back as the coccyx—do not even come in contact with it The levator lifts the rectum and vagina forward and upward to the pubic arch The muscle has but limited influence on the sides of the rectum The muscular fibers composing the horseshoe loop exercise the chief influence over the rectum, while the portion of the muscle arising from the white line (fascia) serves its purpose by holding the pelvic diaphragm in relation prepared for any immediate action, with its superior and inferior fascia it makes a tense floor for the superimposed viscera

The levator ani fascia superior and inferior lends the muscle its greatest utility by increasing its strength and also producing harmonious action in its function The horseshoe sling is inseparably blended with the sphincter ani externus The levator ani produces the H-shaped condition of the vagina and its puckered or constricted appearance at the orifice The muscle becomes hypertrophied during pregnancy and vaginismus It resists the head in labor to a surprising degree It may be easily observed in slow labor, when, if small forceps sufficient to overcome the tension of the muscle be applied, labor proceeds rapidly

The comparison of the diaphragm and levator ani, as to the capacity for strength, is in favor of the levator ani Its strength varies much in different subjects

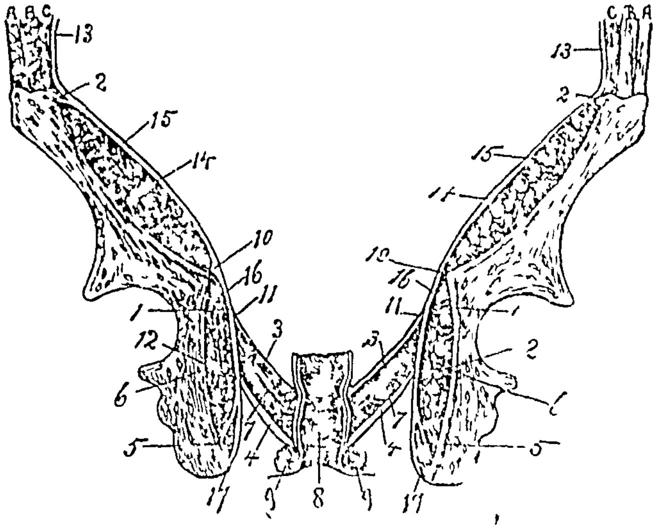

Fig 7—(Robinson Scholer) A diagram to illustrate the pelvic fascia, with a new nomenclature of same 1, 1, white line 2 2, origin of transversalis and iliac fascia at the iliac crest 3 3 levator ani fascia superior 4 4, levator ani fascia inferior 5 5, Alcock's canal 6, 6 obturator internus muscle 7, 7, levator ani muscle, 8, vagina or rectum 9 external sphincter 10 10, ileopectineal line 11, 11, origin of levator ani fascia superior 12, 12 beginning of obturator fascia inferior 13 13, transversalis fascia, 14 14, iliac muscle 15, 15, iliac fascia 16 16, obturator fascia superior, 17, 17, ending of obturator fascia inferior on the ischial tuberosity

The best descriptions of the levator ani muscle are given by Henle, Luschka, Testut and Lesshaft Hart and Dickinson have made excellent studies on this muscle Browning wrote an interesting article on the subject The levator ani may be a rudimentary muscle, disappearing with the tail and in the evolutionary process of an erect attitude This view may arise from the weakness of its origin, the direction of its fibers and insertion, as well as the requirement of the double fasciæ It is unphysiologic for a muscle to produce constant support, hence the levator ani can not be considered a support for the viscera, it is rather a sphincter muscle

The levator ani muscle is analogous to the buccinator muscle Perhaps from an evolutionary standpoint we may look on the levator ani as having three functions, viz *a*, of a sphincter, *b*, of an elevator, and *c*, of a tensor of the levator ani fascia, superior and inferior

As proof that the levator ani is a sphincter, one need only introduce the finger into the vagina and request the subject to contract the muscle Cruveilhier, Henle, Lesshaft and Budge insist that the levator ani is a sphincter of the anus and lower rectum chiefly, and not an elevator That this muscle is an elevator one need only dissect it to find the muscle ending definitely in the walls of the rectum, and such terminating fibers, when in action, could only elevate the rectum The horse in defecation illustrates that the levator ani is an elevator, as the rectal wall is elevated, the rectal mucosa everted and completely evacuated As an elevator, it resists intra-abdominal pressure

The levator ani appears as well developed in the male as the female, and hence labor does not appear to develop it The levator ani muscle is greater in those animals with a tail, and originally its chief function was to aid in managing the tail, from which it would appear that as a tensor of the levator ani fascia superior and inferior, these fibers take an active part They originate at a definite fixed point, lose themselves between the fascial blades and do not reach rectal or vaginal walls When a muscular fiber neither goes to the rectum nor ends in its wall, it will not act as a sphincter, nor as an elevator

Lesshaft and Roux divide the levator ani into two layers, viz , *a*, the inner layer, which is an elevator and *b*, the outer layer which is a sphincter

THE INTERNAL PELVIC FASCIA

The internal fascia of the lesser pelvis has a poor literature, and is not often described As the pelvic fascia has much to do with the permanent results of the flap or any perineal operation, I will write of it somewhat in detail

The fascia of the greater pelvis, or that fascia lying superior to the ileopectineal line, is not here considered The fasciæ, the planes of strong, fibrous tissue here under consideration, lie below the ileopectineal line

As a teacher of anatomy, I have always maintained that a fascia should be named according to the muscle or other structure with which it is in the most intimate relation I shall therefore apply this simple nomenclature to the fascia in the pelvis

The fascia covering the obturator internus muscle will be termed the obturator fascia As this fascia is divided by the white line extending from the posterior surface of the pubis to the ischial spine, we will call that portion of the fascia above the white line, the obturator fascia superior, and that portion of the fascia below the white line, the obturator fascia inferior The fascia above the levator ani, originally named by Tyrrell the rectovesicale, and by Carcassone the pelvic aponeurosis, by others the vesical layer of the pelvic fascia, we will name the levator ani fascia superior, and that part of the fascia below the levator ani, the levator ani fascia inferior The fascia covering the coccygeal and pyriformis muscles will be named after those muscles The fascia covering the sacrum very naturally takes the name of the sacral fascia The internal fascia of the lesser pelvis extends from the iliopectineal line on either side to the median raphe of the pelvic floor It not only lines the pelvic walls and floor, but enters into intimate relations with the pelvic viscera It is a strong, shiny fibrous membrane, possessing a very varying quantity and quality In a certain sense the fascia of the lesser pelvis should be treated as an independent structure, and not as a continuation of the iliac transversalis or other fasciæ The ileopectineal line marks an absolute division between the iliac and obturator fascia

The simplest plan is to describe the obturator fascia superior and inferior and to consider the obturator fascia as distinctly belonging to the obturator (internus) muscle, subsequently to consider the fascia of the levator ani superior and inferior, with a lesser consideration of the coccygeus pyriformis and sacral fasciæ The fasciæ lining the lesser pelvis are intimately connected with their respective associated muscles and structures by strong connective tissue The connection of the fasciæ with the peritoneum is not intimate a thick, loose layer of connective tissue richly laden with fat lobules, lies between the peritoneum and the fasciæ lining the lesser pelvis This loose connection of pelvic peritoneum and pelvic fasciæ allows the easy and rapid spread of pelvic abscesses between the pelvic fasciæ and the peritoneum in the subperitoneal tissue

The obturator internus fascia surrounds the obturator muscle at its origin, from the lateral pelvic surface of the innominate bone, and is the special fascia of the obturator internus muscle It is attached for a considerable distance to the iliac portions of the brim At this point the obturator becomes attached to the upper border of the obturator membrane In front the attached line of the fascia passes below the ileopectineal line to allow the obturator vessels and the nerve to enter the obturator foramen or canal This portion is fixed to the periosteum and appears as an independent organ In front it is attached to the body of the pubis and along the upper margin of the obturator foramen by an oblique line, to a point about one half an inch below the symphysis Where the fascia dips under to allow the passage of the obturator vessels and nerves it is firmly attached to the periosteum and nerves by strong tendinous fibers Posteriorly, it is attached to the anterior surface of the great sacrosciatic ligament and the anterior margin of the great sacrosciatic notch Inferiorly, the fascia is attached to the margin of the obturator foramen of the descending ramus of the pubis, and it joins the falciform process of the great sacrosciatic ligament, which firmly connects it to the inner border of the ischium and its ascending ramus

With a firm insertion in the ileopectineal line, the

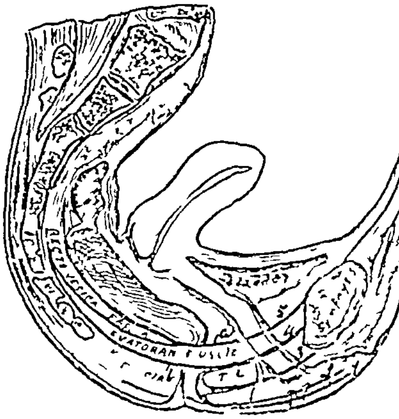

Fig 8—(Ranney) Diagram of the fascia of the pelvic floor in a mesial section It illustrates the levator ani fascia superior and inferior above and below the levator ani muscle T L triangular ligament I F two layers of superficial perineal fascia Observe that in the anterior triangular perineal space there are five layers of fascia, viz 1 superficial layer of perineal fascia 2 deep layer of superficial perineal fascia 3 triangular ligament outer layer 4 triangular ligament inner layer levator ani fascia superior In the posterior perineal space there are two layers of fascia—the levator ani fascia superior and the levator ani fascia inferior

anterior border of the great sacrosciatic foramen, the anterior and inferior margin of the obturator foramen and to the edge of the falciform process of the great sacrosciatic ligament, the obturator fascia becomes a fixed, strong, thick, fibrous membrane in relation superiorly with the obturator nerve and vessels and inferiorly with the *internal pudic* vessels and nerves —Alcock's canal It has intimate attachments to the obturator internus muscle above, but is quite loose below

The obturator fascia we divide into two portions, superior and inferior The obturator fascia superior is that portion above the white line or arcus tendineus It looks into the pelvic cavity from the lateral aspect and is covered by peritoneum The peritoneum and obturator fascia superior are separated by considerable loose, fatless, snow-white connective tissue, composed of many shiny, thin, cleavable planes, which become easily dissected by progress of the pelvic abscesses

The structures of importance which pass over the internal face of the obturator fascia superior just below the iliopectineal line are the obturator vessels and nerves These structures are liable to be injured by the head soon after its engagement by the brim or fixed bony ring of the pelvis The obturator fascia superior has a surface of about ten square inches

The obturator fascia inferior is that portion below the arcus tendineus or white line It looks internally into the ischiorectal fossa and externally toward the r internus muscle It forms the external of the ischiorectal fossa At the lower part chiorectal fossa about an inch above the osity of the ischium the obturator fascia planes me separated, producing a sheath — Alcock's al — for the transmission of the pubic vessels and nerves The obturator fascia inferior, has a surface of some five square inches one-half the size of the obturator fascia superior

At the lesser sciatic notch, the obturator fascia passes out of the pelvis with the muscles and gains the postero-femoral regions of the thigh The obturator fascia is inserted into the ramus of the ischium and pubis, where it passes on and blends with the triangular ligament of the urethra, hence the triangular ligament is a continuation of the obturator fascia from each side

The arcus tendineus or white line appears as an aggregation of tendinous fibers of the obturator fascia It extends from the posterior surface of the pubis to the spine of the ischium It possesses a gentle curve with its concavity upward The white line gives origin to that part of the levator ani muscle, which arises between the lower posterior surface of the pubis and ischial spine The white line arises out of the ligaments of the bladder, a thickened portion of the obturator fascia is the line of origin of two planes of fasciæ The upper plane I call the levator ani fascia superior, and the lower plane the levator ani fascia inferior The white line varies in thickness in individuals—generally is one-sixth of an inch in thickness in the middle, but its greatest strength and width is at the anterior end, where it assumes intimate relations with the pubovesical ligaments In women the white line is about four inches long Its origin at the pubis may be chiefly from the anterior and lateral (true) ligaments of the bladder The white line allows considerable elasticity It is quite firmly fixed at the anterior end, and definitely at the posterior end, but, like a long, tight rope, allows considerable range of motion and sagging in the middle

The levator ani fascia superior (rectovesical fascia of Tyrell, rectovesical aponeurosis of Carassone or visceral layer of the pelvic fascia) arises from the white line and passing inward forms the floor of the pelvis The levator ani fascia superior, as its name implies, covers the superior surface of the levator ani muscle The fascia finally loses itself in the median raphe behind the rectum in the rectal, vaginal and vesical walls, and in the anterior and lateral ligaments of the bladder From this relation, the levator ani fascia superior becomes of significant interest in perineorrhaphy Anteriorly it is remarkably strong and short, being attached to the back of the pubis above the obturator fascia from which it is separated by the origin of the levator ani muscle, the levator ani fascia superior, the levator ani muscle and the obturator fascia being all three closely adherent to the pubis bone and to each other

If one carefully removes the peritoneum and loose subperitoneal tissue the levator ani fascia superior may be plainly seen stretching from the white line to the bladder, vagina and rectum It may be stripped off the levator ani muscle in several thin, cleavable planes It is reflected on the bladder forming the anterior true and lateral true ligament of the bladder, however the lateral ligaments of the bladder may be assisted by ligaments from the vagina The levator ani fascia superior begins its anterior attachments at the lower border of the symphysis, continues then along the white line laterally to the ischial spine, continues from the ischial spine on the superior surface of the levator ani muscle to the median raphe The levator ani fascia superior covers an area of about six square inches on each side of the median line of the pelvis

The levator ani fascia superior may be divided into the anterior or vesical portion, the vaginal portion and the rectal portion

The vesical portion of the levator ani fascia superior is reflected from the pubis to the neck of the bladder, forming the anterior true ligaments of the bladder and part of the lateral ligaments The vesical portion is very thick and strong, even tendinous It is reflected from the pubis in an arched manner The vaginal portion of the levator ani fascia superior is analogous to that which surrounds the prostate in the male In the male the prostate gland and vesiculæ seminales are surrounded by a strong capsule derived from levator ani fascia superior This portion of fascia surrounds the vagina in the female, including *the large venous plexuses*

(To be continued)

THE INVASION OF PORTO RICO FROM A MEDICAL STANDPOINT

BY N SENN, LIEUT COL U S V

CHIEF OF THE OPERATING STAFF WITH THE ARMY IN THE FIELD

The occupation of Cuba and the Philippine Islands by our conquering navy and army in such rapid succession seemed to increase the desire of conquest and opportunities to test the strength of our arms With the destruction of the weak navy of our enemy there was nothing in the way of sending troops to any of the many Spanish possessions The fall of the heroic Cervera and his faithful little band, off the harbor of Santiago, before the murderous fire of our well equipped fleet cleared the pathways of the ocean of further sources of danger It was but natural that the beautiful island of Porto Rico one of Spain's most valuable possessions should have been selected by the military authorities as the next objective point for contention Repeated attacks by our navy on its best stronghold, San Juan, had failed to bring about surrender and to gain a foothold on Porto Rican soil So far the navy had taken the lead in bringing Spain to terms and the army was anxious to do its share in wresting from its greedy grasp another enslaved people Major General Miles, who conducted the invasion in person, decided to march upon San Juan from several directions, and, after uniting the forces, attack the city jointly The experience gained in Cuba had taught us an important lesson in conducting the Porto Rican campaign General Miles laid his plans wisely and with special reference to gain the desired object with as little suffering and loss of life as possible Every movement in this campaign was made with a due regard for the welfare and success of our troops rather than a desire for personal gain and aggrandizement, which characterized the Cuban campaign as every one knows He was well aware of the depressing effects of the tropical climate on the unseasoned troops and of the necessity of resorting to timely and efficient precautions in preventing disease From experience and personal observations, he recognized the fact that the unavoidable privations incident to warfare are multiplied many times when the seat of war is a strange and remote country presenting a climate and environments unaccustomed to by the invading force His actions were clean cut admissions that he was in need of a medical adviser and that they were influenced by the frequent consultations held with his chief surgeon The war in Porto Rico was conducted upon the most humane principles, and although no great battles were fought, victory upon victory followed the footsteps of our army and in less than three weeks our flag floated over three of the largest cities of the island Our troops love and respect their leader and have followed him without fear and grumbling under the scorching sun, full of confidence and trust The news that peace had been declared reached the headquarters at Ponce, August 14, and the troops are now resting on their arms awaiting the final adjustment of the terms of peace Eager to fight, yet every soldier in the field received this message of peace with joy and enthusiasm, fully satisfied that the army had done justice to the flag and country it represents Col Charles R Greenleaf, chief surgeon of the army in the field accompanied General Miles on his trip from Guantanamo to Porto Rico, and has been with the army ever since He was long enough in Cuba to gain a full insight into the horrors created by infectious diseases, which so constantly follow large armies, especially in a war of invasion He was amazed when he saw to what extent yellow fever had broken out in the few weeks the troops had been in Cuba There was no difficulty in tracing the disease to a total lack of precaution on the part of the general in command Col Greenleaf had given his directions and advice before the army left Tampa, but they were not heeded Owing to want of co operation on part of General Shafter, the medical officers found themselves powerless in preventing and combating the dreaded disease Col Greenleaf's prompt and energetic action on his arrival in Cuba did much in repressing this disease but it was too late too guard against a general outbreak The many recent graves in Cuba containing the remains of the victims of this disease are the best proof of what will happen when the leader of an army ignores the health and comfort of his men In planning the Porto Rican invasion, General Miles availed himself of the invaluable services of his chief surgeon The expedition was well supplied with medicines, hospital stores and medical officers to meet all possible emergencies The result has been that the army has been so far singularly exempt from disease with the exception of typhoid fever and the effects of heat, both beyond the control of the medical officers Since his arrival in Ponce, Col Greenleaf has been the busiest man in the army He has not been content in simply issuing his orders from headquarters but he has attended in person to the execution of every detail He has visited the camps and the hospitals and exercised personal oversight over the distribution of hospital supplies instruments and medicines Anxious to serve the sick and wounded impatient when face to face with a slow, hesitating subordinate, he has more than once performed temporarily the duties of an ordinary hospital steward to furnish a much needed object-lesson His work will justify the confidence reposed in him when he was appointed to the high and responsible position he holds during this war

General Nelson A Miles in command of the Army in Porto Rico By courtesy of McClure's Magazine Copyrighted 1898 by S S McClure Co

FIRST SKIRMISH

General Miles landed with his expedition which included a number of vessels at Guanica Monday

July 25 The harbor was entered by the now famous little gunboat *Gloucester*, under the command of Lieut-Commander Wainwright A landing was effected by thirty sailors, the Spanish flag was hauled down, and the stars and stripes raised amid the cheers of the sailors, who knew well that what they had just witnessed meant liberty and freedom for the downtrodden people of the island of which they had just taken possession

The planting of the flag and the deafening cheers which reechoed from the hills of the liberated island were followed by a volley from the hidden enemy, which was promptly responded to by the guns of the *Gloucester* and a Colt rapid fire gun, which had been taken ashore The Spaniards fled in confusion and sought shelter among the adjacent hills leaving four killed on the field, while our soldiers escaped without a scratch The turn of the infantry came soon after landing, in the form of a lively skirmish, in which we lost one killed and fifteen wounded, of whom one died a day or two later Most of the injuries were flesh wounds, which healed in a remarkably short time A very interesting incident occurred during this skirmish The day was hot, and our troops had to ascend a steep hill, from the crest of which the Spaniards defended themselves One of the volunteer soldiers, outrunning his comrades advanced far ahead of his line and when he nearly had reached the Spanish position was overcome by heat He fell in a semi-conscious state A Spanish doctor rushed to his aid with a stretcher and two hospital corps men, administered necessary restoratives and had him conveyed at within our line This one act alone goes to show the Spaniards have often been unjustly accused eing cruel and inhuman This certainly has not een the case during the present war From my own observations I am sure that they have respected the Red Cross In fact, the Red Cross people of Porto Rico, composed largely of Spaniards, have shown the greatest activity and interest in their humane work during the entire campaign If anything, they have rather been overzealous, judging from the number of insignia displayed and worn It was a common thing to see men wear a white cap with an immense red cross on top, another one in front, besides the brassard

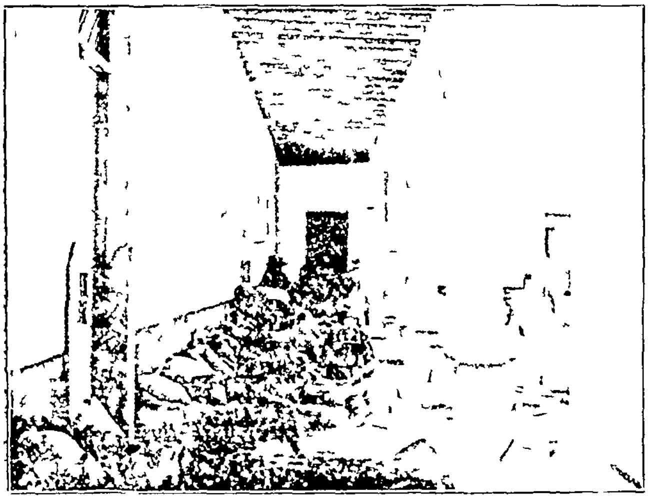
Ponce was taken and occupied without any resistance whatever The citizens received our soldiers with enthusiasm and manifestations of joy General Miles was hailed as a long-looked-for friend rather than a conqueror The next engagement occurred between Arroya and Guayama, between a small Spanish force in ambush and General Haines' brigade, and resulted in eleven wounded on our side The only death following this skirmish was a soldier of the Third Illinois Infantry who was shot accidentally by an unknown man of the Fourth Pennsylvania regiment The bullet caused an extensive non-penetrating injury of the chest, from the effects of which he died the next day Such accidents have occurred too often during the present war, and to prevent repetition in the future this matter should be investigated, as was done in this instance, by the proper authorities Among the injured was a man who was shot through the pelvis and another one the subject of a gunshot wound of the elbow joint, both of them doing well four days later when I examined the wounded in the brigade hospital at Guayama The third skirmish took place between the advance column of General Wilson's division, on the march to San Juan, and a small Spanish force intrenched on the summit of a high and steep hill Lieut Haines, the son of General Haines, was the only one who was brought on board the *Relief* August 4 One of the wounded was operated on by Dr Parkhill in an ambulance The abdomen was torn open by a fragment of a shell, the intestines protruded and a resection had to be made of a loop for a tearing injury It was reported that the patient rallied well from the immediate effects of the operation and that hopes were entertained of his recovery Another engagement took place between the troops under command of General Schwan, on their way from Ponce to Mayaguez, and about 1000 Spaniards ambushed four miles from the latter city This fight resulted in two killed and eighteen wounded on our side All of the wounded were brought on board the hospital ship *Relief*, which called at Mayaguez on her way to New York, August 15 Such is a brief account of the casualties sustained by our army during the Porto Rican campaign The experience here coincided with that gained in Cuba, to the effect of confirming the humane nature of the modern weapon The proportion of killed to wounded is even smaller than in the Cuban war, as well as the number of seriously injured Thanks to more elaborate preparations for the campaign, the wounded received prompt and efficient attention The suffer-

Col Charles R Greenleaf, Chief Surgeon of the Army in the Field ing of the well, sick, and wounded can not be compared with what I saw in Cuba War is a great educator, and should we again be called upon to invade a foreign country, we shall profit by the experience of the past

TYPHOID FEVER IN PORTO RICO

The native doctors in Ponce, Porto Rico, gave us the assurance that not a single case of yellow fever had been seen in that city for the last three years We were informed that in San Juan isolated cases occur from time to time Malaria is present in all of the valleys, more especially in and around Ponce The large, pendulous abdomen and the pale faces of the many little naked children in city and country, are the best witnesses in showing the prevalence of malarial intoxication

Typhoid fever is endemic in certain localities, but at present Ponce is almost free from this disease Having seen the destruction of life and the indescribable suffering caused by yellow fever in Cuba, Col Greenleaf naturally turned his attention toward protecting our troops in Porto Rico against this scourge The proximity of Porto Rico to Cuba, the many possible sources of infection, made such a course imperative That this fear was not unfounded, and that the Chief Surgeon recognized the danger and made use of timely precautions are but shown by the contents of a letter addressed to the Adjutant-General, Headquarters of the Army, and Circular No 1 issued before the army sailed from Guantanamo to Porto Rico, and a copy of the Quarantine Regulations formulated at the same time



Fever patients in the court of the Spanish military hospital

HEADQUARTERS OF THE ARMY,
ON BOARD U S S "YALE," EN ROUTE TO PORTO RICO,
July 23 1898

To the Adjutant General Headquarters of the Army

SIR —I have the honor to submit the following recommendations for preventing as far as possible the introduction of yellow fever into the command now about to land on the island of Porto Rico

The assignment of an officer of rank to be placed in command of the base of supplies with authority to indicate the sites to be occupied by the various supply depots and the hospital, and to enforce the regulations governing the health of the attachés of these departments and the persons who may visit them on business

The assignment of a sanitary inspector whose duty it shall be to examine all vessels and persons arriving at our base from seaward ports and to prepare sanitary regulations for the Government of all transportation and persons arriving and departing from the station by land This officer should have authority to quarantine all suspicious persons and means of transportation, and to disinfect their belongings, either by fire or such other means as may be deemed necessary

All persons connected with the Army are forbidden to enter any building whatever on the island without express authority from these headquarters, and all buildings in rural districts that may be suspected of harboring the germs of disease should be destroyed by fire or otherwise thoroughly disinfected

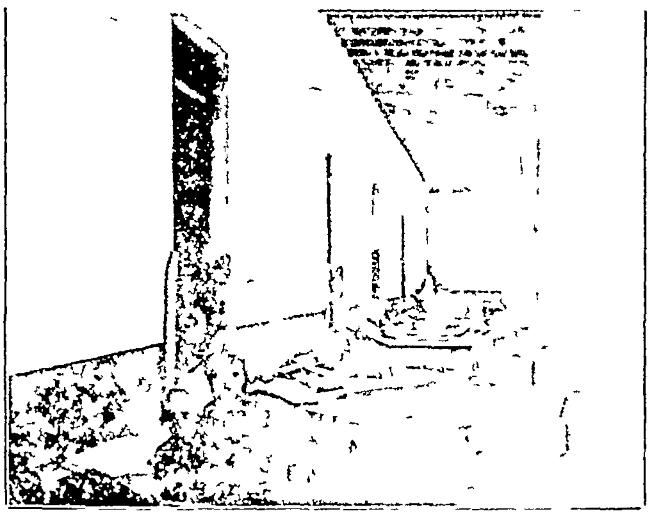
As woven goods, particularly those of woolen fabric are special carriers of disease, the purchase or acceptance of articles of this kind from stores or inhabitants of the island is strictly forbidden Any such property found within the lines will be at once destroyed and the holder subjected to punishment

That commanders of regiments be instructed to prepare their camping grounds with great care and maintain a rigid police in them, under no circumstances shall they camp on ground that has previously been occupied either by troops or by collective bodies of the inhabitants

That medical officers be required to make frequent inspections of the commands to which they belong, and that any suspicious case of fever be immediately isolated and the fact of its occurrence reported to these headquarters

Canteens should be filled daily with tea or coffee, and these beverages used habitually instead of water, unless that has been previously boiled Very Respectfully,

CHAS R GREENLEAF, Colonel,
Asst Surg Genl U S A , Chief Surg Army in the Field



Fever patients in the court of the Spanish military hospital

HEADQUARTERS OF THE ARMY,
OFFICE OF THE CHIEF SURGEON, ON BOARD U S S "YALE,"
EN ROUTE TO PORTO RICO
July 21, 1898

Circular No 1

1 Medical officers will, upon receipt of this circular, report to the Chief Surgeon of the Army the number of medical officers, hospital stewards, acting hospital stewards and privates of the Hospital Corps on duty with their command Also the number of ambulances, litters and tents, and if medical supplies are insufficient, note the general character needed This report will be made upon the following form

Command	Med Offs	Hosp Stwd	Acts H S	Privates	Litters	Ambulance	Hosp Tent	Character of Medical Supplies Needed

2 A field hospital will be organized at the Army base as soon as possible after landing, and a depot of supplies will be connected with it As we are widely separated from the source of our supplies a strict economy in their use is necessary Surgeons of Divisions and Brigades will give their personal attention to this important subject.

3 Extreme vigilance is enjoined upon Medical Officers in the matter of camp sanitation errors in this particular being promptly reported to the respective commanding officer

4 The experience at Santiago has demonstrated the efficiency of properly applied first dressings to [illegible] these should be left untouched until the patient arrives at the base hospital unless the condition of the wound absolutely demands a redressing en route from the first dressing station All diagnosis tags will be carried [illegible]

or "Redressing required," as the condition demands Unless an imperative necessity exists, surgical operations will not be attempted at the front

Chas R Greenleaf, Colonel,
Asst Surg Gen U S A , Chief Surg Army in the Field

QUARANTINE REGULATIONS FOR THE BASE OF THE MILITARY EXPEDITION TO PORTO RICO

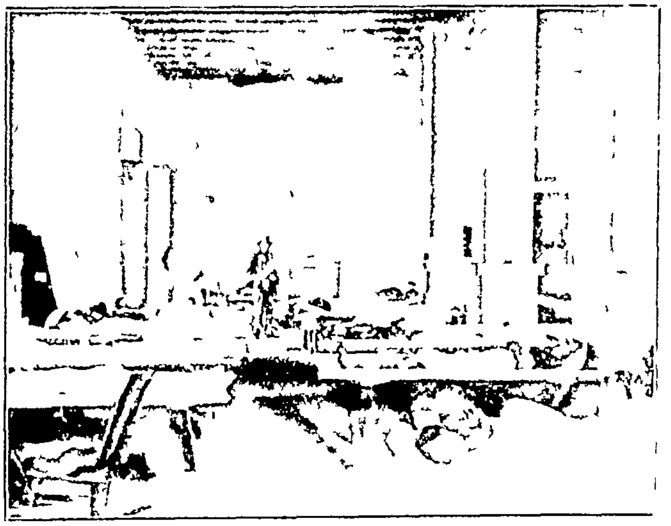
1 Every vessel shall be officially visited by the inspector before communication is made with other vessels or with the shore

2 A vessel having yellow fever or smallpox on board shall not be allowed to communicate with the shore, or with other vessels, but shall leave the island

3 Vessels coming from sources of infection shall be detained five days without communicating either with the shore or with other vessels If at the expiration of this time no cases of fever shall have developed, landing may be made under the following precautions

All fomites shall be disinfected by one of the following methods Immersion for one hour in 1 1000 solution bichlorid, sulphur fumigation in a chamber twenty four hours, four pounds of sulphur being used for each 1000 cubic feet of space, or boiling half an hour with complete immersion The following need not be disinfected unless directly exposed to infection

All new and dry material unpacked, all iron and steel implements, all goods in new and original packages, not having been broken or packed in an infected locality Goods other than textile contained in textile material, such as coffee in sacks, bacon, spices, etc, kept dry and not broken in an infected locality do not require disinfection other than the container, which shall be treated as fomites as above Fruits, sound, unless exposed in an infected locality need no disinfection Live stock may be admitted



Ward in the Spanish military hospital

Such ships shall be thoroughly cleaned and disinfected by the free use of 1 1000 solution of bichlorid, and by fumigation with sulphur before they may again receive men or supplies

Ships quarantined shall display the usual flag, and those in detention shall be visited by the inspector daily until the time of quarantine shall have expired

4 Vessels carrying passengers or having fomites from localities of infection, though they (the vessels) may hail from healthy ports, shall be subject to the same quarantine restrictions as vessels known to hail from infected localities

5 Due precaution shall be taken to prevent infection of the base of supplies through communication with infected localities along the line of march by teamsters and others As far as possible they should not be allowed to remain at the base longer than necessary to load and unload, nor to come in such contact as to communicate infection Stragglers, prisoners and strangers should be immediately sent away

Chas R Greenleaf, Colonel,
Asst Surg Gen U S A , Chief Surg Army in the Field

Major Woodbury was appointed Sanitary Inspector He met with the hearty co-operation of the city authorities of Ponce in the performance of his onerous and often unpleasant duties The sanitary conditions of the city underwent a great improvement in a few days The water-supply was found satisfactory The absence of a sewerage system threw many obstacles in the way The appearance of smallpox in a village some distance from Ponce made vaccination among the soldiers who were not protected against this disease and the natives necessary An abundant supply of vaccine virus was on hand and was at once issued and used When I arrived at Ponce, August 7, I found typhoid fever raging to an alarming extent. It was desirable to trace the origin of the disease The absence of typhoid fever this season of the year, its outbreak in all the commands, and the short time that had intervened between leaving the United States and the landing in Porto Rico made it probable that the disease could be traced to the infected camps occupied by the troops before leaving for Porto Rico General Miles was very anxious to obtain reliable information regarding the origin and spread of the disease Pursuant to the following order I made an exhaustive and systematic investigation

Headquarters of the Army, Office of the Chief Surgeon.
Port Ponce, Porto Rico, Aug 10, 1898

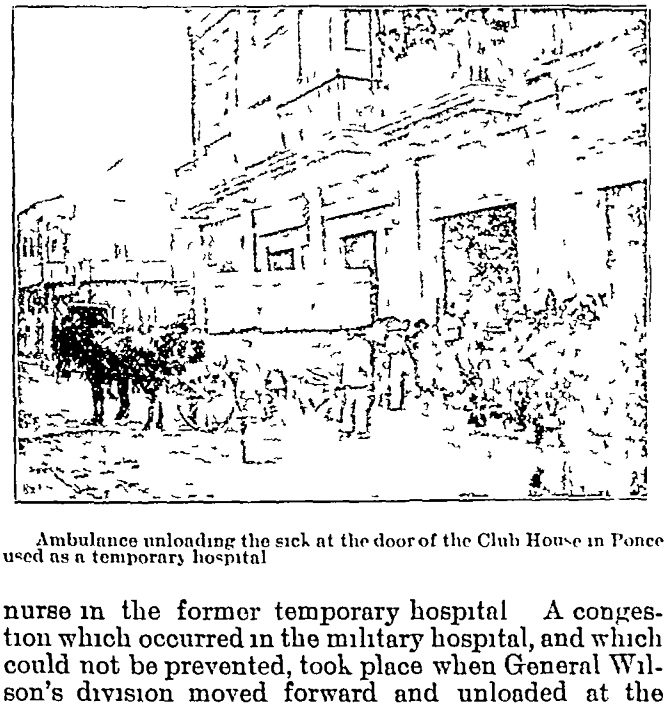
Lieut. Col Nicholas Senn, Surgeon U S V , Chief of Operating Staff of the Army

Sir —You will proceed to the town of Ponce, visit the military and other hospitals in that town, and such of the camps in its vicinity as you may deem necessary, for the purpose of investigating and, if possible, determining the cause of typhoid and other fevers now prevailing in this army, and report the results of your investigation in writing to me Should you find it necessary to have the services of an interpreter, or other civilian, to aid in your work, you are hereby authorized to employ him, sending the bill to this office for payment

Very respectfully,
Chas R Greenleaf, Colonel,
Asst Surg Gen U S A , Chief Surg Army in the Field

Ambulance train transporting the sick from the Division Hospital to the Spanish military hospital

I obtained accurate information of two hundred fever patients, of which number more than 90 per cent were well-marked typhoid fever, the balance malaria and the results of sunstroke I estimated the whole number of fever patients in, and in the immediate vicinity of, Ponce at 250 In extending my inquiries to General Brooke's command, with headquarters at Guayama, I found about 145 additional cases, however, in that locality malaria seemed to predominate Most of the cases came from Chickamauga by way of Charleston and Newport News The Second and Third Wisconsin Regiments furnished the largest contingent Almost every soldier in the different hospitals belonging to either of these regiments suffered from typical typhoid fever, and what attracted my attention was that the disease appeared to be of a more serious type than in most of the men belonging to other regiments The locality from which these regiments came, when encamped at Chickamauga, must have been badly infected As the result of my investigations, I reported to Col Greenleaf the number of cases found, and that in my opinion the disease was contracted in every instance before leaving the camps in the United States In view of the fact that most of the cases came from Chickamauga, I suggested at the same time that the Medical Department should recommend immediate evacuation of that camp In Ponce most of the cases found shelter and care in the Spanish military hospital, then in charge of Major Ten Eyck, U S A The club house and a school for girls, of the Sisters of Charity, were also placed at the disposal of the chief surgeon and were soon filled with patients Miss Chancellor of New York did excellent service as a nurse in the former temporary hospital A congestion which occurred in the military hospital, and which could not be prevented, took place when General Wilson's division moved forward and unloaded at the door all of the sick in the Division hospital, some 150 in number The overcrowded condition was remedied the next day, when a large number of the more grave cases were sent on board the *Relief*, anchored in the harbor of Ponce Medical supplies were in abundance at all times and were freely issued without any formality The *Relief*, and later the yacht *May* brought an additional supply, with many delicacies for the sick Milk was bought and freely supplied to the sick It is the intention of the chief surgeon to establish an extensive out-door receiving hospital as soon as the tentage arrives, which, according to information received from the Surgeon-General is now on the way The number of new cases of typhoid fever in the Porto Rican army will probably be a limited one, and if the troops are recalled as soon as the treaty of peace has been signed, we need to entertain little fear of the indigenous spread of the disease



Ambulance unloading the sick at the door of the Club House in Ponce used as a temporary hospital

Arroyo, Porto Rico, Aug 12, 1898

TYPHOID FEVER IN THE PORTO RICAN CAMPAIGN

BY N SENN LIEUT COL U S V

CHIEF OF OPERATING STAFF WITH THE ARMY IN THE FIELD

[Written for the JOURNAL exclusively]

In Cuba our army met as its most formidable enemy one of the most dreaded of all infectious diseases—yellow fever The Cuban invasion was characterized by hasty action a lack of organization, and inadequate preparation The last crippled the medical department and is responsible for the early and extensive outbreak of yellow fever In less than two weeks after our army landed in Cuba, yellow fever made its appearance, and almost simultaneously attacked the troops from Siboney, the base of invasion, to the trenches before Santiago In less than two weeks from its appearance nearly 500 fever cases, most of them yellow fever, impaired the fighting force and seriously taxed the limited resources of the medical department Fortunately for the army, that type of the disease was mild, the number of deaths few as compared with some of the epidemics in the past Under the circumstances, it was fortunate that Santiago surrendered in time, as the fighting force was being rapidly reduced by the invasion of yellow fever and the ever-present malaria In planning the Porto Rican invasion the possible repetition of a similar experience was taken into due consideration, and timely precautions against such an occurrence were adopted and carried into effect So far our troops in Porto Rico have escaped yellow fever, but soon after their landing, fever cases came into the hospitals at an alarming rate Many of the soldiers were attacked on the transports or soon after landing After landing in Ponce, August 8, I found at least 250 cases of fever in the different hospitals in the city and the division hospital near the city limits Even a superficial examination sufficed to prove that most of the cases were typhoid fever The time which intervened between the departure of the troops from the United States and the appearance of fever, made it more than probable that the infection did not have an indigenous origin In some of the cases it was difficult, in others impossible, to make a differential diagnosis between malaria and typhoid fever without the use of the microscope, and this invaluable diagnostic resource in such cases was unfortunately not at hand Another difficulty we had to contend with was the lack of recorded thermometric observations, which, when accurately made and systematically recorded, prove of such signal service in distinguishing between these two febrile conditions

Pursuant to an order issued by Col Greenleaf, chief surgeon of the army in the field I investigated for two consecutive days all of the fever cases then in the hospitals, for the purpose of locating the origin of typhoid fever In this work I availed myself of the kind and able assistance of Dr M O Terry, Surgeon-General of the State of New York, and Acting Assistant Surgeon Greenleaf, son of the chief surgeon We made a careful examination of 200 cases of fever as they presented themselves noted the principal symptoms and tabulated them (see following page)

A careful study of these cases as well as subsequent developments, furnished adequate proof that 90 per cent of them were genuine typhoid fever No further doubt could remain in tracing the infection to the camps occupied in the United States The great

prevalence of the disease among the troops, affecting as it did, more or less, all of the regiments, was a source of uneasiness and anxiety on the part of those who were in charge of the invasion Measures were taken to secure ample hospital room and facilities for the accommodation and proper treatment of those on hand and such as might be brought in later The order to General Wilson to take up the march toward San Juan made it necessary to evacuate the division hospital All of the patients were transferred to the Spanish military hospital in Ponce, which caused the temporary overcrowding to which I referred in a former communication The Spanish military hospital is a substantial, square, one story building with a large court in the center It is built of stone, the floors being made of cement or brick tiling It is on a high hill near the city limits, from which a magnificent view of the city, harbor and surrounding country can be obtained It has a capacity for about 150 beds It required a good deal of labor to make this building fit for the reception of patients Major Dooly and his force worked persistently a whole day in removing the dirt and filth which the Spaniards had left, in their haste in evacuating the city, as an undesirable legacy The hospital was at once supplied with cots, bedding and hospital stores The club-house of the

city and a school for girls in charge of the Sisters of Charity, were offered to the authorities for hospital use, and courtesy was promptly accepted For over a week the sick officers occupied the club-house and about fifty patients found comfortable quarters and excellent treatment in the school-house Ponce has a large charity hospital, the "Tricoche with 200 beds under the care and management of the Sisters of Charity The hospital is a model of cleanliness and comfort Col Greenleaf made arrangements with the city authorities to open the doors of this excellent institution for sick officers I am sure that every one who will enjoy the kind treatment and excellent care of the Sisters in these great institutions of charity will have a good word for this ancient and worthy order Out of the 200 cases of fever examined in the different hospitals in Ponce and which appear in the table, the following diagnoses were made at the time Gastric fever, 2 effects of sunstroke 6 malaria 9 doubtful 21 typhoid fever, 162--total, 200

I am satisfied that of the doubtful cases a sufficient number developed typhoid fever to bring the whole number of cases up to 180 In reference to the time the disease developed the following can be gleaned from the table The first symptoms appeared before leaving the United States, 8 on transports [illegible] within ten days after landing, 68, out of a total of 162

As regards the place of infection the cases came from Chickamauga, 90, Tampa, 48, Camp Alger, 23, Newport News, 1—total, 162

The small number coming from Camp Alger, where the disease gained such a firm foothold, which led to the abandonment of the camp, is to be explained by the fact that a large number of fever cases, coming from that camp, were returned to the United States soon after landing, by order of Col Greenleaf All regiments were not affected alike by this disease Among the troops in Porto Rico the typhoid fever cases were distributed as follows

2d Wisconsin	42
3d Wisconsin	17
16th Pennsylvania	17
6th Massachusetts	15
19th U S Infantry	15
6th Illinois	11
3d Artillery	10
4th Artillery	5
11th U S Infantry	5
1st Provisional Corps	4
Hospital Corps	1
17th U S Infantry	3
2d Cavalry	3
5th Cavalry	3
3d Illinois	4
1th Pennsylvania	2
Signal Corps	2
5th Artillery	1
Total	162

In tabulating the symptoms the following facts appear

Tongue	Dry, coated, red at tip and margin	10
	Coated, white fur	21
	Coated, pale, flabby	17
	Coated, red tip and margin	56
	Dry, brown and fissured	20
	Moist, glazed, red	13
	Sordes, lips and teeth	12
Abdomen	Tympanites	29
	Tenderness and gurgling right iliac fossa	71
	Rose spots	37
	Spleen enlarged	141
	Spleen markedly enlarged	20
Epistaxis during prodromal stage		28
Diarrhea		87
Intestinal hemorrhage		3
Bronchitis		20
Delirium		1

The absence of delirium in all cases but one is remarkable, but it must not be forgotten that nearly all of the cases were examined during the early stages of the disease In quite a number of cases this symptom appeared later From the symptoms and the death-rate, ascertainable at this time, it is evident that the disease pursued a comparatively mild course Nearly 200 of the more grave cases were transferred to the hospital ship *Relief*, which sailed from Ponce for New York August 15 Of this number fourteen died en route and twelve were buried at sea In two of these cases death resulted from complications In one case gangrene of the penis, which assumed a progressive form, was the direct cause of death In one case a fatal termination threatened during the third week of the disease from laryngitis and lobular pneumonia A metastatic abscess of the submaxillary gland, which developed in one case, deserves mention as a rare complication of typhoid fever

RETURN OF THE HOSPITAL SHIP "RELIEF" FROM PORTO RICO

The *Relief* sailed from Ponce, Porto Rico, August 15, for New York, and called on her way at Mayaguez to complete her precious cargo of sick and wounded All of the wounded at the last port were taken on board The entire number of patients on leaving Porto Rico was 255, the full capacity of the floating hospital It is probably the first time in the history of the world that so many fever cases were treated on a hospital ship and conveyed from a foreign country to their homes The first day out a brisk breeze caused considerable rolling and pitching of the ship, which induced some cases of seasickness among the patients, but did not seem to unfavorably influence the disease The female nurses worked faithfully and proved of the utmost value to the sick Fourteen of the more severe cases of typhoid fever died on the way to New York Many of the patients improved rapidly during the voyage The *Relief* has done all and more than was expected in serving as a temporary hospital and as an ambulance ship in the treatment and transportation of the sick and wounded

New York, Aug 20, 1898

SOCIETY PROCEEDINGS

The Fourth International Congress for the Study of Tuberculosis

Held at Paris, July 27 to August 2

The Congress was not distinguished by any striking communication, but showed a general awakening on the part of the public and the authorities in many countries, to the necessity of prophylaxis in regard to tuberculosis The official resolutions adopted by the Congress have already been published in the JOURNAL, page 483 It is remarkable that France is behind the rest in the matter of legislation requiring isolation of infected cattle Norway is the most advanced of the European countries in this respect, but has very few animals infected She requires animals seriously affected to be slaughtered at once, and animals that react to tuberculin to be branded and only sold for slaughter No indemnity is paid to the owners The regulations in Denmark are somewhat similar, but the owner receives an indemnity of one quarter to one half the value of the animal when condemned by the inspector The calf of a tuberculous cow must also be taken away from her and raised on milk that is boiled, or from a healthy cow The proportion of tuberculous calves has fallen from 15 5 in 1895, to 10 6 Professor Bang of Copenhagen delivered the address on this subject and stated that the rigorous measures adopted are bearing fruit, as the disease is not increasing, but the reverse He considers the *first* tuberculin test the most reliable, and adds that animals should rest a few days after a journey or other exertion, as otherwise the test is not trustworthy It is not infallible at the best The regulation has quite recently been adopted in Denmark, that no dairy can sell skimmed or buttermilk without first heating it to 85 degrees C, which does not affect the taste of any milk if cooled rapidly afterward The Danish law of March 26 requires the immediate slaughter of a cow affected with tuberculous mammitis Siegen of Luxenburg urged the more general adoption of the practice of sterilizing very much infected meat by cooking with steam under pressure at 110 to 125 degrees C for two or three hours, as is now done in some places in Germany and Holland The meat and gravy thus obtained is nutritious and savory, and is eagerly purchased by the poor at half a franc the kilo No other process actually sterilizes meat from animals with generalized tuberculosis Magnan of Nice described the fine results obtained there by giving official certificates to dairies found free from tuberculosis, with tags for the animals to wear that had passed the tuberculin test He hopes to get the daily papers to call attention to these model dairies often, and the public to patronize them, also to have the public institutions refuse to purchase milk except from certified cows

The members of the Congress first gathered at the new model Boucicaut Hospital, where they witnessed the operation of the frigor or crymotherapeutic service which is fulfilling expectations and brings back the appetite, even in the most pronounced cases of anexoria (*vide* JOURNAL, xxx, 1116) The ozone generator was also inspected, and a couple of meetings during the Congress were devoted to radioscopy and radiography of tuberculous subjects by skilled experts Finsen's treatment of

"Lupus with Concentrated Light" was also described at one meeting, with projections (*vide* JOURNAL, August 6) The address of the President, Professor Nocard, stated that out of 140,000 deaths every year from tuberculosis in France, 100,000 could be averted if contagion could be prevented The difficulties of

HOME DISINFECTION AMONG THE POOR

were graphically portrayed by MARTIN, who described the work accomplished in a certain quarter of Paris where 100 tuberculous subjects resided Their rooms, linen, etc , were disinfected every week, but from lack of fuel to make a fire, the subjects were frequently unable to sterilize daily the cuspidors provided, and frequently they had no linen to disinfect In some cases they were turned out of doors by the family from fear of contagion E Guiter of Cannes described the success of the measures adopted along the Riviera to prevent contagion The out of door life in the sunshine minimizes the danger, and the chambers of tuberculous patients are built to be flooded with sunshine, dry sweeping is prevented as much as possible, all unnecessary drapery and padded furniture is banished, hygienic cuspidors are in universal use, with pocket cuspidors for each patient who seems to be favorably impressed by them (Dettweiler, Vaquier or Petit models) The Medical Society of Cannes has organized a disinfecting service, not only for rooms in which deaths have occurred, but for those occupied temporarily by persons with "open tuberculosis", all transportable articles that will not be injured by steam under pressure, are disinfected in a Heischer and Geneste sterilizer the toilet stand, marbles, etc are washed with sublimate, and the room disinfected with formol vapors generated by a Trillat autoclave, one liter of 38 per cent formo chlorol to each hundred cubic meters, the contact prolonged twelve hours The experiences of Berlioz, Nicolle, Rietsch and Aronson have established the practical value of formo chlorol for this purpose (see especially the *Marseilles Méd* Nov 1, 1897) Disinfection in this manner has been performed 258 times at Cannes during the season or 1898 The physician notifies the proprietor on a slip furnished by the Board of Health, when he considers disinfection necessary The proprietor notifies the disinfecting service, which proceeds to the task under the supervision of a city emplové The Board of Health then remits to the physician his original slip, signed by the disinfecting officer, thus securing a dual supervision, municipal and medical

Dr HIRSCHFELDER described his Oxytuberculin, summarizing his communications to the JOURNAL in the last volume In several of the addresses his name was coupled with Behring's and Koch's, when speaking of recent improvements in tuberculin He reports seventy cases successfully treated, and stated that the oxytuberculin also cures local tuberculosis

THE MODEL SANITARIUM

was discussed from every point of view Bernheim recommends a large central building, with two pavilions connected by wide galleries, with immense piazzas facing the south The bed rooms also face the south, and are finished like a surgeon's operating room The building is planned for 360 patients, two in each room, and if a four months' residence is sufficient, 1080 can be accommodated during the year The isolation of tuberculous patients in the hospitals is an important and beneficial measure, now being carried out at the Boucicaut but it is incomplete and cruel unless supplemented by country sanatoria to which patients can be transferred As Letulle observed "the sanitorium will prove the hope of those who are waiting their chance to go there, the delight of those who enter and find themselves regaining health, and a school of hygiene and prophylaxis for all who are so fortunate as to have passed through it"

Prof LANDOUZY delivered an address on the

PRESENT STATUS OF SERUMATED TOXIN TREATMENT OF TUBERCULOSIS

concluding "the conclusions of Koch in regard to the results accomplished by his new tuberculin T R, have not been confirmed by others, even restricting its use, as he insists, to the non febrile forms It is generally acknowledged to be harmless, and to have a favorable effect on the general health but its action on the tuberculous lesions is less easily established Its effect on cutaneous tuberculosis is more decided, and the determatologists of Germany and England unite in proclaiming that the facts already observed justify further investigation Koch has succeeded in depriving his first tuberculin of its deleterious properties Others have modified it, like Hirschfelder, by oxidizing it, or by passing it through the blood of an animal to accumulate antitoxic properties, like Maragliano Broca and Charrin have also secured favorable results with injections of serum from dogs inoculated with tuberculosis, in patients with surgical tuberculosis Babes and Proca have also succeeded in manufacturing a serum by injecting animals in turn with tuberculin and dead bacilli which has proved immunizing and bactericidal *in vitro* Behring believes that the combination of the resources of serum and toxin therapeutics will, in some distant future, lead to the discovery of the specific remedy for tuberculosis, and Maragliano adds that every effort should be applied to hasten the day Behring has succeeded in curing a tuberculous cow with repeated injections, and he found that the serum of this cow contained a new substance, a true antitoxin of tuberculosis, as her serum would neutralize a considerable dose of specific toxin He is at present engaged in investigating whether certain kinds of birds are not better adapted to the production of a tuberculosis antitoxin than mammals He dissolves the mucin with sodium to extract the toxin from the bacillus more readily, and also dissolves the fatty matters with ether or chloroform, obtaining thus a tuberculin so powerful that one gram will kill 12,500 grams in healthy guinea pigs (*vide* JOURNAL, xxx, 1482) But even admitting that serum or toxin treatment, or both, will ever produce an actually specific remedy for tuberculosis, we must not expect of it more than it is able to accomplish, i e, the cure of the specific lesions, and of these alone This treatment will never be able to cure the secondary infections that invade the tuberculous foci as soon as they become "open" Hence, this specific treatment will never be really effective except in the first stage of the disease It is evident, therefore, that hygiene will always retain its importance in the treatment of tuberculosis, which, even at the best, is more easily avoided than cured"

Prof Fournier called attention to the danger of ascribing to tuberculosis what does not really belong to it, and cited an instructive case of mutilating syphilis of the extremities long supposed to be a tuberculous affection Gallot of Menton reported his remarkable success in curing repeated hemoptysis in the early stages of tuberculosis with hypodermic injections of iodoform as follows oil of neutral vaselin, 25 centigrams, eucalyptol, 5 grams, iodoform, 75 centigrams Inject two centigrams daily Boureau of Tours has found phosphoric acid combined with creosote very effective in improving the general condition of tuberculous subjects It creates an artificial hyperacidity like that of arthritism, thus modifying the hypoacid tendency which is a favorable soil for tuberculosis Calot proclaimed the value of puncture and injections of camphorated naphthol and iodoformed ether in tuberculous arthritis except of the hip joint Reporting thirty nine out of forty cases cured without surgical intervention M Desprez of Saint Quentin again confirmed the value of small doses of chloroform combined with hygienic measures in the treatment of tuberculosis and appealed to others to test this "harmless and truly marvelous antibacillary substance" in epidemic and contagious diseases especially tuberculosis Berlioz of Grenoble announced marked improvement in the general health and gain in weight,—12 kilos in three months in one case, and 4 kilos in fifteen days in another, in a large number of tuberculous patients he has been treating with a medicated serum consisting of normal beef serum, phosphate of guaiacol and extracts of the testes, liver, brain, lungs, thus combining sero and opotherapeutics He administers 30 grams a day of this mixture, per rectum, and finds the sweats, expectoration and cough subside with the remarkable improvement in the general condition He continues the treatment several weeks or months Fever is not a counterindication Two febrile cases thus treated showed the same subsidence of the symptoms as the others

SELECTIONS

Ancient Medical Fees—Bombaugh presents a study on "Medical Fees in Ancient Greece and Rome" in the *Johns Hopkins Hospital Bulletin*, for August The first such fee of which he finds specific record was one recorded by *Herodotus* as given by Darius to Democedes of Crotona a slave of Oroetes and consisting of two pairs of fetters of gold "In his day in Greece, the usual fee paid to physicians for incidental visits was very small, in fact not more than two groats sixteen cents or about one thirtieth of the customary fee in England in our time, one guinea." It was customary for physicians to be engaged by the year by the municipality, and paid *from* public funds In Ægina Democedes received one talent a year about £[illegible] in Athens his salary for a year was 100 minæ [illegible] later receiving a like sum when residing at Samos According to

United States 'Pharmacopeia'?" the total number of answers was, 298, affirmative, 238, negative, 60, non committal, 5, no answers, 8 Some answered "Yes, they have come to stay" "Yes, in proper hands valuable" "Yes, with due discrimination" "Yes, where nature and mode of manufacture is known" "Yes, if they can be sufficiently defined" "Yes, the most important ones" "Yes, acetanalid only" "No, except antifebrin" "If they do only in an appendix" "Not without formulæ" "Not till we know more about them in every way"

To question 8, "Shall antitoxin serum be given a place in the United States 'Pharmacopeia'?" the total number of answers was 293, affirmative, 224, negative, 69, non committal 5, no answer, 13 Some say "Pehaps so, although I do not consider it as reliable a remedy as some do" "Antitoxin serum will probably not be used ten years hence, but while it is used *the manufactory should* be watched" "Yes, especially diphtheritic" "Yes, if it can be sufficiently defined" Yes, one standard" "Not till its value is fully and definitely determined" "No, druggists should keep on hand and dispense closed packages" "No, unless more exactness is obtained" "Emphatic—no Classify them as poisons and place with their class"

To question 9, "Shall fermented and distilled liquors be dismissed from the United States 'Pharmacopeia'?" the total number of answers was 287, affirmative, 67, negative, 220, non committal, 2, no answer, 22 Some said "Yes, except alcohol" "Yes, as I consider them very seldom indicated and very often used improperly" "So *far as possible* they should" The two non committals give interrogation points as answers

To question 10, "Are you in favor of introducing the metric system in prescribing?" there were 301 answers, affirmative, 138, negative, 163, non committal, 4, no answers, 6 Some say "Yes, but not discarding the old while our people continue to think in 1/4, 1/3, 1/2, etc, instead of 1/5, 1/10, 1/100, etc" "Yes, when done by an act of Congress, for it is of the utmost importance, and to avoid mistakes" "Yes, if made universal" "Yes, for all except grains and fractions thereof, i e no decimals" "Yes, if made compulsory by law" "Yes, I think it the most correct system" "Yes," *think both should* be given in the United States 'Pharmacopeia'" "Yes, both systems should be used" "Decidedly As I am an American and our system suits me, let others come to ours if they so desire" "It should be optional for a time, but certainly would be best, and no doubt will be fully adopted" "Established it in the St Louis City Hospital many years ago Have used it exclusively ever since 'in practice'" 'I have never been able to see any great advantage in it" "Not to the exclusion of the old system" "Not until generally used by law of Congress" "Hundreds of physicians do not understand it and would cause many serious mistakes All who desire can use it anyway Therefore leave the old system in vogue and all will be pleased" "No, errors in dispensing would be multiplied by use of the metric system" "No, English for Americans" "No, America good enough" "No, no, it's un-American" "No!!! Be Americans and for God's sake quit aping other nations It's no more scientific than our own" "Not to make it compulsory upon the physician or to exclude the use of the old weights and measures" "No, I am in favor of more light being given the intelligent public than now obtains There is far too much empiricism" "No, but the system should be given and taught in our schools"

Lamaistic Practice Among the Mongols —A French army surgeon, J J Matignon, resident at Pekin, has given an account of Mongolian medicine, based on information received from a native who was for a time physician to the living Buddha of Ourga, an important town some 800 miles northwest of the Chinese capital Medicine among the *Mongols* is a monopoly of the Lamas There is a school of medicine at Ourga, where, after a prolonged course of philosophy and Buddhist theology, three years are given to the study of the art of healing Mongolian medicine is largely derived from Chinese and, through that, from European medicine as it was two centuries ago The European strain comes *from the old treatises translated* into Chinese by the Jesuits in the reigns of the Emperors Kien Long and Kan si Mongols do not dissect, and their knowledge even of the position of the internal organs is vague The number of diseases is fixed at 440 Works on medicine are very numerous, the chief one being a kind of encyclopedia, entitled "Khlantap," which is divided into eight sections and consists of 156 chapters Their methods of physical examination are full of marvels Thus more than seventy varieties of pulse are described The urine is examined with great minuteness in respect to its color, smell, and clearness, samples passed at many different hours of the day being used It is also subjected to a kind of *auscultation, being beaten with a wooden* spatula, and the vessel then quickly applied to the ear In the case of rich patients the examination is made more thorough by tasting, a procedure which naturally is made the ground of a special charge

Mongols, like practitioners of former days in Europe, profess to be able to diagnose and treat all sorts of cases on the strength of an examination of the urine alone The treatment is largely internal, and their pharmacopeia is mainly composed of vegetable substances Every year, in September, the students make excursions under the direction of their teachers, for the purpose of culling samples, which are dried, classified and catalogued *Aromatic plants, such as* cinnamon and benzoin, play a large part in their thereapeutics Animal and mineral substances are also used but to a much less extent The Mongol doctor carries his drugs about with him Each medicament, dried and triturated, is put into a small leather bag, which is properly labelled, some practitioners carry as many as three hundred of these bags enclosed in a larger one, or in a box with a spoon to measure the doses Like the ecclesiastic physicians of the Middle Ages, the Lamas are forbidden to practice surgery, although in cases of crushed limbs or other severe injury necessitating amputation, they may direct a butcher how to use a knife They practice venesection, however, use poultices for the maturation of abscesses, and vigorous massage for the relief of headache and other pains Recent wounds are dressed with lichen of the steppes or with deer fat They use counter irritation by moxas, acupuncture and ignipuncture, and they practice wet-cupping by *means of ox horns*

Preparations of sulphur and lead are used as applications in diseases of the skin, and bathing in hot sulphur springs, in syphilis Fish's bile is credited with the power of curing cataract Human bile, and that of the bear and of the hyena, also *frequently enter into the composition of their medical* preparations Mongol doctors seek to restore vigor to old men by the internal administration of ram's testicles "Organo therapy" is also employed Thus, the flesh of the sheep is given for vertigo, that of the antelope for diarrhea, that of the water rat for nephritis and dropsy, *that of the marmot for dys*menorrhea, that of the beaver for spinal disease and impotence, that of the wolf in diseases of the stomach They are acquainted with the parasiticide properties of mercury, and use it to destroy the vermin with which their countrymen are generally infected The most prevalent diseases at Ourga are syphilis and skin affections, but typhus, typhoid, malaria, and other fevers are very common In treating fevers they purge with rhubarb, and when that fails they give enemata or suppositories, the latter being composed of salt and sugar They also give nux vomica sudorifics, and ginger, and juniper is burnt round about the patient Cholera is treated chiefly by acupuncture under the nails, on the tongue, and around the anus, and as a last resource by burning the pit of the stomach

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE

Per Annum in Advance	$5 00
Foreign Postage	2 00
Single Copies	10 Cents

In requesting change of address give old as well as new location

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No 61 Market Street (Occidental Bldgs) Chicago Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman 100 Washington St Chicago Ill sending him a certificate or statement that the applicant is in good standing in his own Society signed by the President and Secretary of said Society Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor* and all communications relative to the business of the JOURNAL proof sheets returned or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL

SATURDAY, SEPTEMBER 10, 1898

CONCERNING THE IODIN REACTION (FLORENCE'S REACTION) WITH SEMINAL AND OTHER FLUIDS

Three or four years ago FLORENCE[1] of Lyons secured a peculiar formation of crystals when semen was brought into contact with concentrated solutions of iodin While he failed to find this reaction in other fluids from the human body and in semen from animals, he nevertheless wisely refrained from claiming an absolutely diagnostic importance for these crystals He looked upon the crystals as indicating the probable presence of semen, and that in such cases one should look so much more carefully for the absolutely positive evidence, namely, the presence of spermatozoa

The medicolegal importance of demonstrating that stains are due to seminal fluid is of course very great The investigations of FLORENCE were painstaking and extensive, and his results have received abundant corroboration In America, W JOHNSTON and WHITNEY[2] have studied the reaction extensively RICHTER[3] tried all the substances which are demonstrable in the semen, and obtained the iodin reaction only with lecithin and cholin He also found the reaction occasionally in decomposing body fluids, and expressed the suspicion it did not concern any specific body but the presence of lecithin and cholin

GUMPRECHT[4] has attempted to more closely demonstrate the chemic nature of the body which leads to the formation of the crystals

The technic of FLORENCE's reaction is very simple The solution consists of water, 30 parts iodin, 1 65 parts, potassium iodid, 2 54 parts Other iodin solutions do not give as constant results The reaction is produced under the cover-glass The drop of iodin solution is placed upon the slide a drop of spermatic fluid, or a watery extract of a suspicious spot, is placed near by, and then the cover-glass is so placed that the line of contact of the two fluids meets near its center At the point of contact of the two fluids there is immediately formed a layer of granules and crystals The crystals are in reality of a long, rhombic form, about three times as long as broad Sometimes they are much longer and look like needles These crystals are brown in color

The most important peculiarity of the crystals is their dichroism They separate polarized light in their long axis, but allow it to pass through in their transverse axis The slight polarization of the reflected light from the mirror or the microscope is sufficient to enable one to recognize this characteristic optic phenomenon in connection with many crystals dark color when the long axis is placed parallel with the entrance of the light, and light coffee-brown color when the long axis is placed transversely to the direction in which the light enters the field

The substance in question was found to be soluble in water, alcohol, ether and chloroform Lecithin resembles this body in its solubility, and GUMPRECHT corroborates the fact demonstrated by RICHTER that lecithin gives the reaction But lecithin nevertheless differs from this body in the semen in so far as it is not soluble in water, but only swells up, and also in the fact that it is precipitated by chlorid of cadmium It was further found that fresh lecithin mixtures did not give the reaction, so that it seemed only natural to suppose that the body is not lecithin itself, but a derivative of that substance

Further experiments showed that in all probability the body which caused the reaction is very closely related to cholin, which can be derived from lecithin Lecithin is ubiquitous, and it therefore seemed peculiar that a derivative of lecithin should be found in the spermatic fluid and not in other tissues The explanation of this problem is to be found in the degree of disintegration of the lecithin and in the concentration of the fluids GUMPRECHT found that a whole series of human tissues and secretions give the iodin reaction very beautifully as soon as the splitting up of the lecithin takes place and the solution becomes sufficiently concentrated from evaporation He therefore reaches the conclusion that this reaction is dependent upon a certain period or step in the lecithin disintegration and about the same period at which cholin appears

In spermatic fluid even the fresh this state of affairs is physiologic and so cholin is demonstrable by the usual reagents In manifold other fluids and tissues containing lecithin, the necessary splitting up of the compound can be produced artificially or through bacterial influences (decomposition) The small amount of albumin in semen in all probability favors the appearance of the iodin reaction, whereas in other fluids, such as pus, sputum, milk, and the fluid of organs, the large percentage of albumin rather prevents the reaction

[3] Wiener kl Wochenschr 189[illegible]
[4] Centralbl f Path Anat 1898 No 14 and 1[illegible]

Having thus, in a measure at any rate, cleared up the reaction, it remains to examine into its medico-legal importance fresh *semen and dried seminal spots*, even of considerable age, have always been found to give positive reaction, decomposed semen, as well as *older solutions of semen even when not decomposed*, give none or but a feeble reaction The juice of the testicle and the contents of the seminal vesicles give *no reaction*, the juice of the prostate varies in its behavior Organs from the cadaver, such as the brain, thymus, spleen, kidney, liver, often give the reaction, even very soon after death Sputum, pus and fat do not give the reaction, except after preparatory treatment with Ba2(HO), it would seem, then, that the value of the reaction in the preliminary study of seminal spots can not be denied Its value in the positive as well as in the negative direction becomes, however, somwhat limited on account of decomposition, which may destroy the reaction in the seminal fluid, and which may produce the reaction in other organs and fluids of the body Furthermore, there are very many other substances outside the body, such as plants, butter, and eggs, which in a decomposing condition, may give the reaction, and this would seem to be the greatest weakness of the test, because butter, eggs, as well as various vegetable substances, often give rise to spots upon clothing, a fact which should never be lost sight of in studying suspicious stains

BRACES IN SPINAL CURVATURE

What greater mistake can there be in medicine than that of fitting a brace to a child suffering from spinal curvature? Yet this very mistake is repeatedly made by both physician and instrument-maker, to the extreme misfortune and permanent deformity of the child There are in medicine and surgery a number of conditions which are hidden from observation and palpation, perhaps they are further obscured by a feeling of uncertainty in the anatomy of the part, and at no time in the course of the disease can we see, feel or measure in millimeters the exact extent of the lesion The physician will invariably draw down the curtain of obscurity before such a case lose his clearness of vision and make haphazard thrusts at both diagnosis and treatment Such a region is the spine It is very difficult to examine the spine, the part that is usually diseased (the body of the vertebræ) it is impossible at any time to palpate, and nerve symptoms are characteristically confusing In an uncertain case of skin disease we may make a diagnosis of eczema and be correct in a large percentage of cases, but in diseases of the spine we *may not* make a diagnosis of tubercular caries because it likewise is a common affection of the spinal column The two conditions of tubercular caries and spinal curvature differ so widely in their causation, symptomatology and treatment that each must have a clear-cut picture in our mind when examining spinal cases

Tubercular caries is a condition of osteomyelitis of the bodies of the vertebræ caused by the presence and growth of the tubercle bacillus There is a progressive destruction of the supporting column of the body and an invariable train of symptoms must follow These symptoms are, briefly a reflex rigidity of the muscles to fix the affected region, pain in the distribution of the nerves emerging from such vertebral segments, pain on motion, preventing the child from stepping hard or jumping, fixation of the spine the child holds to furniture as it walks around, angular deformity in an antero-posterior plane, lastly, abscess and paralysis from characteristic features of the later stages of the disease While no age or class of children is exempt from spinal tuberculosis, it is found most frequently in poorly nourished children between the ages of three and ten years

Lateral curvature of the spine, on the other hand, is, as a rule, not a disease of the vertebræ, but a lack of symmetry between the two sides, with a rotation of the bodies of the vertebræ on a vertical axis The causes of such a condition possess such decided importance, and are best divided into predisposing and exciting causes The predisposing causes are prolonged ill-health, rapid growth and rickets occurring in girls between 12 and 20 years, while the exciting causes may be a one-sided position at school, a faulty position in standing, an obliquity in the pelvis, and it would seem from the fact that it is usually right-sided that a hypertrophy of the muscles on this side acts as a prominent factor The symptoms of this disease are likewise at variance with those of Pott's disease The first symptom is noticed by the dressmaker, who finds it necessary to pad one shoulder She observes an "angel wing" (a prominent scapula) or a high hip, and very soon a prominence of the ribs on one side appears because of a rotation of the vertebræ on their vertical axis At once a lack of symmetry is produced between the two iliocostal spaces, the one deep, the other long, and an S curve made by the spinous processes completes the picture There is no pain at any time, no tenderness on pressure no fixation of the spine, the curvature is always lateral and paralysis or abscess never appears The one point that these two conditions have in common is the involvement of the spine

What folly, what total lack of reason it would seem then, to put a splint on a weak muscle! The fault is entirely one of nutrition and development The ligaments are lax and insecure, the muscular development on one side is greater than that on the other, and a natural result from such inequality of forces will be a shortening on the side of greatest muscular power When the condition is once established, the added leverage only serves to increase the deformity Indications for treatment are positive An out door life in a tonic atmosphere, regular hours for eating and sleeping, baths, no apparatus and systematic gymnastic exercise prescribed by a physician, represent the measures best calculated to give results Apparatus only defeats the objects of the treatment in a great majority of cases, by preventing development, and apparatus, no matter how skillfully constructed, can not correct a deformity of this kind

THE CURABILITY OF EPILEPSY

Epilepsy, which is commonly treated of as a spinal disease in the text-books, is also there usually considered as a curable one, at least to a certain extent Practically, however, well marked cases in adults are commonly estimated as incurable, and there are neurologists who seem disinclined to admit even the small percentage of recoveries that others allow as possible Dr **Wharton Sinkler**, for example, in a recently published paper, appears to take the ground that a suspension of epileptic symptoms for a term of many years is to be considered rather as a remission than a cure, in fact, he apparently considers it hardly justifiable to put down any case as cured He has collected a series of twenty-four cases altogether, in which the epileptic symptoms failed to reappear for various periods ranging from two to twenty-nine years, including eight cases in which they were lacking from five to nine years, and four cases of even longer intervals The surprising feature in his figures is that they do not include a larger proportion of cases with the shorter intervals of two and three years, which it would appear ought to be more common than those of the longer periods, and this suggests the possibility that these latter include some of those instances that are not so infrequent after all, when a single epileptic attack, or possibly a series of such occur at a certain time in an individual's life, it may be under some special toxic influence or condition of mental or bodily over-strain, and then fail to recur, perhaps for the remaining period of his existence Almost every one, it would seem, who has had large experience with epileptics ought to have met with some of these cases, and it is not uncommon even in asylums, where the patients are under close observation, to meet with cases counted as mild dements in whom an occasional epileptic attack occurs at intervals of several, or possibly a number of years Such cases are not commonly considered as cases of cured epilepsy, or sometimes are hardly reckoned among the epileptics in the classification of the institution There are still other cases known to asylum physicians, where epilepsy has passed into chronic insanity, sometimes of the delusional type without any pronounced dementia and which has continued for many years, indeed through the whole remaining life of the patient without any epileptic symptoms whatever

When we consider what epilepsy really is viz, a symptom or a collection of symptoms of cortical irritability or excitability, in all probability dependent upon a very wide range of pathologic conditions, from irreparable organic changes on the one hand to slight vasomotor disturbances from various causes on the other, there seems to be no good *a priori* reason for holding it to be invariably incurable It would appear indeed, more reasonable to admit that what is pathologically indistinguishable from epilepsy that undergoes recovery should be classed with epilepsy, and that well-marked cases of the disorder may therefore be counted as curable The infant's cortex is particularly unstable, it may be irritated to the extent of producing general convulsive phenomena with every symptom of epilepsy in the adult, and yet its recuperative power and developmental possibilities are such that it does not by any means follow that infantile eclampsia implies later epilepsy They are practically the same thing, and the distinction that is made between them is a purely arbitrary one based on the fact that one is recovered from, while the other, as a rule, is not, there is certainly a logical defect in every argument for the incurability of epilepsy founded upon such a distinction as this In children past the age of actual infancy the progress of epilepsy is still relatively favorable, and most practitioners of experience with nervous diseases have had cases in such that they felt justified in considering as cured The more complete the development of the brain, the more serious is the prognosis as a rule in the disorder, it is true that we do not often meet with a cure of so called idiopathic epilepsy in the adult, and yet it would be unjustifiable to say that it does not sometimes occur The question is what we shall call a recovery according to Dr G M **Hammond**, in the discussion of Dr **Sinkler's** paper in the American Neurological Association, a complete absence of epileptic symptoms for the space of three years ought to be reckoned as a cure, and any subsequent recurrence should be considered as another attack from a different cause There is reason in this, though others might demand a larger interval of freedom from symptoms, it is usually little more rational to call such an occurrence in epilepsy a remission than it would be to say that the interval between a first and a second attack of pneumonia, for example, is a remission The morbid excitability of the cerebral cortex, of which epilepsy is a manifestation, once allayed, the patient is practically well and there is no inherent presumption against the permanency of the recovery If external irritation could be avoided the cures would be more numerous, but the continuance of an even slightly greater susceptibility to excitation than is exactly normal renders a relapse the more possible In a certain proportion of cases, not a large one it is true, there undoubtedly is a restoration to an approximately normal condition, and there is reason to think that in a smaller proportion the morbid process may produce an obtunding instead of an aggravation of the excitability thus tending to dementia or insanity without characteristic epileptic phenomena In the majority of cases, however, the epileptic symptoms continue in spite of the brain deterioration and the disorder is accounted as incurable

The proportion of actual cures of epilepsy is small Dr **Joseph Collins** estimates it, however, as high as 5 per cent under proper and steady treatment When we take into account the juvenile cases this is probably not too large, and if we include infantile eclampsia in epilepsy, not large enough Add to these the cases where only one or two attacks occur in a lifetime, and the patient survives them many years, even without treatment—and there are many such cases that hardly come under the care of physicians—and the proportion is still further increased

It is beyond question that there is a risk of too early estimation of cures in epilepsy, but three to five years' freedom from attack ought, it would seem, to justify the counting a case as recovered Post operative cures are in fact very commonly reported far within such a length of observation, but they ought to be subject to the same rules as to interval and observation as others, and will not be likely to alter the statistics in the way of making them any more favorable Organic disease and serious developmental defects are probably responsible for the majority of epilepsies, but there remains a proportion that are probably due to conditions that are themselves not altogether incurable, or are at least amenable to treatment, and in these there is at least a possibility of cure Still others are due to temporary intoxications or overstrains, and if there be not irreparable damage set up they may even undergo a spontaneous cure which may escape medical observation The dictum of the incurability of even adult idiopathic epilepsy is, therefore, not fully warranted by observation or based on well-established pathologic facts

THE CHAIR OF PHYSIOLOGIC CHEMISTRY IN MEDICAL COLLEGES

What produces the symptoms of epilepsy, of hysteria, of gout, lithemia, uremia and rheumatism? What is the nature of antitoxin and how is the morbific agent of acute infectious diseases destroyed by its action? We are beginning to know something about pathology, therapeutics, and physical diagnosis, and we know a great deal about anatomy, surgery and bacteriology A system of diseases has been built up from the knowledge of micro-organisms We have reached that point of knowledge in bacteriology, where it becomes possible to extract wax from the tubercle bacillus, to stain its spores and the flagellæ of the bacillus icteroides Sanarelli We believe that typhoid fever is due to the Eberth bacillus and that its introduction into the small intestines gives rise to manifold symptoms But we do not know to what all these symptoms are due. When there is a disturbance of the metabolic activity of the liver, of the pancreas, of the stomach and small intestines in typhoid fever, a complex condition supervenes and it may be an open question whether the toxin given off by the specific organism is in the ascendancy or whether the other ptomains together with leucomains play the principal part If we start out with the proposition that the symptoms of hemicrania, lithemia and asthma are due to uric acid, and the symptoms of uremia to members of the creatinin group of leucomains, we again meet with extreme difficulty in proving the proposition by exact experiment

In the United States two conditions confront the original investigator at the outset 1 There are few laboratories fitted for this work and, 2, there are comparatively few competent to instruct in chemistry from a physiologic standpoint In Germany, where institutions for original research are aided by the Government, and where men are guaranteed a certain income or salary to conduct one series of observations, we necessarily hear a great deal of the "Congress fur innere Medicine," and of "internal medicine," during the summer and winter semesters The migration of medical students to the old world can not be effectually stopped until the teachers in the colleges of North America write the text-books used by those across the water

In our rapid stride, searching for the cause of disease, the department of bacteriology has been pushed with extreme vigor and we become discouraged on further inquiry to find that the cause for the many symptoms of disease lies hidden within a labyrinth of physiologic and chemic problems at present beyond our comprehension The United States does not lack investigators in these problems There are thousands of younger physicians here eager to undertake this work if they only had the training and the opportunity The time has long since passed when, by simply injecting hypodermatically a certain drug, one could ascribe certain definite symptoms as the resultant We have passed beyond that stage, and things are now on a surer foundation capable of withstanding the flings of unrelenting criticism

If we should take an inventory of the different medical colleges in this country in which there is a department of physiologic chemistry, we would find that there would be comparatively few fitted for giving proper instruction in this department, notwithstanding a four-year course is a prerequisite for graduation, and for which necessary expense the student, be it said, should in return get value received The student can not undertake these experiments alone His mind must be under the supervision of one fitted to detect the occluded sparks which lead toward the hidden goal Another thing Those who would undertake to conduct original research in internal medicine, more especially with leucomains for instance, must not be surprised that these all-important bodies can not be purchased in the open market, and that in order to get a few grains of them the first prerequisite is to secure from fifty to seventy-five gallons of urine Truly it must be said that in our zeal for the exploration in other fields in the different medical colleges of the land, the coming study of the day lies buried in the mist which only time and necessity will brush away

Let us have a Department of Public Health!

THE INDIFFERENT ANESTHETIST

There is something essentially wrong in the methods of administering anesthetics when the laity begin to revolt against existing methods and prepare to dictate to the anesthetist how he shall administer an anesthetic During the past few months the *Nineteenth Century* has contained articles condemning certain existing methods of administering chloroform in England, and that of June concludes as follows "Let each one of us refuse resolutely to take chloroform or allow any member of our family to take it without first obtaining a guarantee from the anesthetist that he will administer it in an open cloth held at a given distance from the nose and that the time taken to put us under shall not be less than eight minutes ' There is a further proposition that the violation of any one of these rules be an act punishable by law

The mind of every medical man must needs revolt against the layman dictating methods to the profession and presuming to say that he shall do his business in this way or that Disagreements among doctors as to diagnosis, prognosis and treatment in a given case have done far too much already to give the layman an incredulous mind and furnish him with grounds for criticising the physician in charge because he does not agree in his methods with his (the patient's) preconceived ideas of the proper conduct of the case This attempted dictation as to the administration of chloroform would call for an answer that would confine itself to a dignified request to "mind their own affairs," were it not for the fact that there is a great fault just where the criticism falls and justice does not permit us as medical men to ignore it within the profession The "stiflers" among anesthetists are made the point of attack, and a visit to many of our hospitals will demonstrate just what is meant by the term The fault in this country is for the most part limited to the administration of ether where the most inexcusable indifference to the patient's comfort is often demonstrated The man who gives the anesthetic in a hospital is regularly the youngest man on the staff, a fresh graduate with theoretic teachings alone, or the example of another interne, as his guide The cone, soaked with ether, is crowded down over the patient's face and he makes a courageous effort to stand it for a time Very soon, however, he struggles to save himself from what these patients afterward describe as a feeling of imminent suffocation and death, and gains a breath of fresh air only in those cases where the orderly or orderlies are unable to hold him down When the patient is under, the anesthetist, who has given ether two or three times, wishes to demonstrate to the assembled students and spectators his entire familiarity with etherization by indifferently gazing around the room or at the field of operation, or he exchanges jokes with a bystander This is essentially wrong and it is a wrong to be corrected by the operator himself No operator should permit any man to administer his anesthetics unless he is competent to do so and willing to direct his undivided attention to the patient The suffering of the patient alone is sufficient reason for the gradual administration of any anesthetic, and the dangers, immediate and remote, are sufficiently great to demand the minimum dose and the proper regulation of the dose As long as the system of the hospital internes exists there will continue to be "swell heads," and the operator alone can remedy his fault of feeling that he knows everything about etherization

CORRESPONDENCE

A Defense of Music

CHICAGO, Aug 25, 1898

To the Editor —In the JOURNAL of July 23 appears an editorial upon the "Hygiene of Music," which, while judiciously advising against the abuse of the art, contains some statements that I would like to reply to From the general tone of the article I would almost infer that the writer is one of those unfortunate, over scientifically trained individuals who, in their zeal for "utilitarianism" have lost their artistic sense Darwin, to whom he refers as attributing the love of music to the sexual sense, clearly stated in his own writings, that though he possessed a lively artistic temperament in his youth, his constant application to science had so warped his mental faculties that in later life it was torture for him to read a great novel, and it was simply impossible for him to enjoy a line of Shakespeare I know an individual whose sexual appetite (from his own confession) is as excessive as any I have ever heard of and yet he is absolutely deficient in the sense of music. Libertines and prostitutes are not, as a rule, particularly musical, while, on the other hand, the great composers with some few exceptions, have led lives as virtuous as the average If music is the "food of love,' and love is to be reduced to mere sexuality it can rejoice at least in being in good company in its misery Some scientists reduce man to two appetites the sexual and the alimentary and according [illegible] love friendship dancing music [illegible] and about everything in life that gives enjoyment [illegible] spring of sexuality or gluttony *Homo* [illegible] Weissmann (quoted in the editorial) thinks the musical [illegible] 'abnormal' which is indeed a very [illegible] reach after the teachings of Darwin that music [illegible] that it is even related to the love notes of the birds [illegible] how science does wobble when it attempts to dissect the *beautiful*, or that which is not strictly *utilitarian*! If the sense of music be abnormal, then how many abnormal people there are in this world of ours Perchance the birds and some of the tamer animals that reveal at times a kind of musical sense are also abnormal The clergy tell us that there will be music in heaven, but who would want to be in heaven if it is to be abnormal? Would that the "abnormal" Darwin, if he is so unfortunate to be now where there is music, would only come to the theorizer about heredity, so that for the credit of "science" a better consistency might be obtained between their present hopelessly divergent views, for our logic is inadequate to reason out the harmony between the theories of these men "whose opinions," the editorial writer shows, "are best worthy of respect" If, as Weismann says, "music is a secondary effect on the organs of hearing induced by cultivation," how, pray, does it happen, as Darwin said, that it is a concomitant of sexuality and "analogous to the love notes of song birds" It seems to me somebody's opinion here is *not* "best worthy of respect" It has been agreed by the evolutionists that, in the development of the human race, the musical sense, of all the senses, is the last to have been acquired If my memory serves me, I think they state that it is about thirty thousand years old Surely what the human race has possessed for thirty thousand years can not by this time be so awfully abnormal! The same evolutionists have calculated, I believe, that about 47 per cent of human beings are lacking in the musical sense Therefore, I take it, *a la* Weismann, that the *majority*, 53 per cent must be all abnormals Our lively and entertaining friend, Nordau, would probably rise up with a sneer and exclaim "true," for he seems to find degeneracy and abnormality quite rampant amongst us I marvel, however, that a *scientific* editorial writer should quote Max, for after the same manner Juvenal might be made to testify that there was no virtue whatever in Rome, and Rabelais will prove that every churchman in his day was a libertine and a wine bibber

"Music in itself is not intellectual," says the editorial writer Neither is a quiet stroll on the boulevard, or rowing or tennis or even sleeping, and a goodly number of other things which we do in life, and yet find more or less essential Some things minister to the intellect, even if they are not strictly intellectual Hear what that arch utilitarian, John Stuart Mill, has to say about it "the only one of the imaginative arts in which I had from childhood taken great pleasure was music, the best effect of which (and in this it surpasses, perhaps, every other art) consists in exciting enthusiasm, in winding up to a high pitch those feelings of an elevated kind which are already in the character, but to which this excitement gives a glow and a fervor, which, though transitory at its utmost height, is precious for sustaining them at other times" If intellection is so supreme a desideratum, would it not be well then for some of us to stir up our intellects with music! Almost the first requisite of intellection is imagination One can not think without, to a certain extent, imagining, and all other things being equal, the man with the clearest insight (imagination) will reason the most clearly Faraday, Liebnitz, Dalton, Newton, Columbus, Laplace, and nearly all the *great* scientists were men of vivid imaginations, and with some of them music awakened the imagination and from their imaginings sprung the great intellectual ideas with which they have endowed the world

Again the editorial declares that "one of the greatest poets has said that to appreciate poetry a trace of morbid mentality was essential" Strange that the author should quote a poet, a kind of musical man, against poetry, for one would think he would not care much for what a *poet* says! As a fact, however, he is quoting Macaulay ("Essay on Milton"), who is scarcely "one of the greatest poets" who wrote his "Essay on Milton" when he was a very young man, this being his first essay, and who, according to his writings elsewhere, never intended that his words should be construed as literally as the editorial writer takes them If the musical faculty is "compatible with a profound degree of dementia," so is the mathematical faculty, the memory and almost every department of the mind As an argument for the "morbid mentality" associated with the musical faculty, Blind Tom is about as weak as even the imagination can conceive of For one Blind Tom, who after all represented not the best type of musician, there are thousands of rational beings richly endowed with the musical sense, as witness an army going into battle to the strains of soul stirring music, or a throng of people cheering for Old Glory and singing their patriotic songs Is not that utilitarian enough and are not those people rational enough, to suit our friend, the writer of the editorial? What is after all *utilitarian* and what is *rational*? We hope he will some day give us a definition of these terms so that we may know *exactly* when we are crossing the Rubicon from the useful to the useless, from the rational to the irrational Milton sings

> "There let the pealing organ blow
> To the full voiced choir below
> In service high and anthems clear
> As may with sweetness, through mine ear
> Dissolve me into ecstacies
> And bring all heaven before mine eyes"

And likewise Wordsworth

> "Where music dwells
> Lingering and wandering on, as loath to die,
> Like thoughts whose very sweetness yieldeth proof
> That they were born for immortality"

If such be the office of music, is it therefore less "utilitarian" than the act of cooking, of buying and selling corner lots, of digging trenches and reading stock quotations? Well, perhaps it is, but, frankly, I have seen some real estate men and stock brokers, genuine utilitarians—yea, and even some scientists—men of one idea and that a utilitarian idea—that I strongly suspected of being on the verge of a "*morbid mentality*" more than I ever suspected the whole troop of musical enthusiasts put together I think I have even heard them talk (as for instance in reasoning about some patent medicine and its marvelous curative powers in their own cases) more *irrationally* and less *intellectually* than the great Beethoven or Mozart must have communed with themselves when evolving their sublime symphonies and concertos

Our editorial friend has fallen into the error, too common with scientists, of supposing the merely utilitarian, the tangible, to be of the greatest value St Paul was a great thinker and he declared that the unseen things were eternal So that which stirs the soul—whether it be music or poetry or painting, whatever tends to lofty ideals and noble acts—is utilitarian in the highest and best sense of the term To be sure it may be abused and here the editorial is notably commendable in warning against the abuse of art The readiness with which it may be abused is only another evidence of its nobility The more delicately a watch is constructed, the more carefully it should be handled Because we all do not understand its mechanism and because it is quickly shattered in the bungling hands of some of us let us not condemn it as the offspring of "a morbid mentality" or as not utilitarian, or as always the outcome of sexuality and gluttony When I listen to the depressing, materialistic, utilitarian mutterings of "science," I am inclined to exclaim with Carlyle, "what in these dull immaginative days are the terrors of conscience to the diseases of the liver! Not on morality but on cookery let us build our stronghold, then brandishing our frying pan as censor, let us offer sweet incense to the devil and live at ease on the fat things he has provided for his elect"

L HARRISON METTLER, M D

How to Suppress Quackery

ROLLA, MO, Sept 1, 1898

To the Editor —Ever since the 4th of March, 1897, when Governor Lon V Stephens put his fist to the bill entitled "An act to regulate the practice of the science of healing diseases and injuries without the use of drugs, known as osteopathy," and sent the congratulations by wire, of himself and wife, to the father of the imposition, praising him for "the wonderful advancement he had made in medical science," Missouri has had to confess with shame, that she is the mother of one of the grossest frauds that has ever been imposed upon the sickly and weak minded people This bastard to science has been advertised in the daily and weekly newspapers, and the laity has read only one side, until rational physicians are looked upon as "jealous cranks who oppose scientific progress '

I was a member of the 38th General Assembly of Missouri, when Edward Higbee introduced and championed this freak of science, known as House Bill No 445 I had to suffer the intense pangs of seeing a large majority of the members in both houses misled by an organized lobby telling how that wonderful man at Kirksville cured sore eyes by replacing a nerve on the back of the patient's neck, how he cured consumption instantaneously by stretching the pneumogastric nerve, how he cured Pott's disease by untying the spinal cord, how he made the lame walk by pulling their legs, etc The large vote by which this bill passed both houses only proved the ignorance of the average legislator on medical subjects, and the able manner in which Governor William J Stone wrote his veto to it, proved that Missouri was then fortunate enough to have a Governor possessed of a good education, good judgment, love for the people, and executive ability and nerve enough to do the right, whether it be popular or unpopular Whilst I am a Republican in politics, I do not believe that Governor Stone has received all the honor from rational physicians due him I would like to see every honorable physician in our State keep a life sized portrait of this able statesman hanging in his office, in token of the high appreciation of the medical fraternity for the friend to science and truth But it is not my intention, in this article, to condemn or to eulogize any individual, but to suggest a method by which empiricism, charlatanism, osteo hypno humbug ism, or any other fad or false theory calculated to deceive and swindle the sick, can be suppressed

So long as a rigid "Code of Ethics" prevents educated and honest physicians who strive more to get knowledge of how to relieve the sick, than they do to accumulate wealth, from using the newspapers for the purpose of enlightening the people, quackery will have the advantage, for the people who can read will read, and they will read such things as they find in the newspapers It is not necessary to state that the newspapers contain a large amount of paid for quack advertising, gotten up for the purpose of misleading the sickly and weak minded, and after swindling them out of their last dollar, something that is easily done, when they read only one side, but will not stand the test when the truth is printed, for one word of truth can explode one hundred words of false theory, when properly applied

The method to subdue quackery which I propose is this Let every physician in each county in the State require his candidate for the legislature, to promise that he will vote against all forms of quackery and humbuggery, and that he will vote as advised by the leading physicians of his county and district, on all subjects pertaining to medicine and surgery This promise should be required irrespective of party affiliations, and our party prejudices should never be so strong as to allow us to ever vote for any man who has supported quackery, or who is likely to do so

Partisanship is one thing, and politics is another It is the duty of a physician to exercise a reasonable amount of interest in the politics or government of his State and nation, especially for the protection of citizens in their rights with the preservation and improvement of their morals but he should never become a partisan to the extent of voting for any person who favors charlatanism

Missouri has about 5000 regular physicians This number is sufficient to resent the insults of both political parties, which have been thrust at the regular profession in the 38th and 39th Assemblies, and repeated at the Democratic and Republican State conventions recently held in Springfield and St Louis

If the medical press, the medical societies and the State Board of Health will take a united interest, and furnish to all physicians of our State a list of all men who have supported, or are apt to support, the fads and frauds above mentioned, and furnish a few suggestions on the subject, I think I am safe in predicting that within from two to four years' time osteo hypno humbug ism in Missouri will be numbered with the slain

The following members of the 38th General Assembly supported House Bill No 445, introduced by Edward Higbee, entitled "An Act to Regulate the Practice of the Science of Healing Diseases and Injuries Without the Use of Drugs, Known as Osteopathy

House —Armstrong, Arnett, Atkins, Best, Bittinger, Bothwell, Bourn, Breit, Cape, Carroll, Cherrington Collins, Coppedge, Carroll, Cox, Crisp, Daneri, Davidson, Davis (Taney), Davison, DeFord, Denslow, Drum Dyer, Ferguson, Freeman, Fuson, George, Gill, Gmelich, Griffiths, Grubb, Hammond Harrison, Hart, Higbee, Hinde, Johnston, Jones (Hickory), Jones (Jackson), Julian, Kasey, Kline, Kyler, Lane, Leroy, Lynch, McCollum, McKearley, McKee, McPherson, Marsh, Middleton, Moore (Mississippi), Moore (Stone) Moran, Mueller, Murray, O'Dell, Odneal, Old, Phipps, Porterfield, Pratt, Rohne, Sachse, Sartin, Schoppenhorst, Schumacher, Sherrill Smith (Buchanan), Smith (Howell), Steel, Stickney Sullinger, Swanger, Tartar, Walton, Warner, Wasmeyer Weaver Weinhold, Wetzel, Young (St Fran), Young), Texas, Mr Speaker

Senate —Amelung, Ballard, Bledsoe, Brewer, Busche, Davisson, Drum, Dunn, Kennish, Klene, Lancaster, Landrum Love, Lyman, McClintic, Madison, Morton Mott, O Bannon, Peers, Powers, Seaber, Walker, Williams, Wurdeman, Yeater

The following members of the 39th General Assembly supported the same bill when introduced by Mr Pickler and Mr Seaber

House —Alldredge, Armstrong, Averill, Aydelott, Barnett, Bittinger, Bohart, Bradford, Bradley, Breit, Brueur, Burroughs, Caldwell, Cashion, Christy Clarke, Clymer, Cock, Coffey, Cole, Collins, Cox (Lewis), Cox (Oregon), Crisp, Curry, Daugherty, Davault, Davidson, Davis (Chariton), Denslow, Dougherty, Dunn, Dyer, Ehrhart, Erman Fitzgerald, Frost, Hale, Hamilton, Hart, Hawkins, Hays, Hendrickson, Hess, Hood, Hopkins, Ijams, Jenkins, Johnson (Cooper), Johnson (St Louis), Koch, Kramme, Lee, London, McCullom, McKim, McMonigle, McPherson, Martin (Barton), Martin (Callaway), Mashburn, Moeller, Morris, Mueller Neville, O Dell, O'Fallon, Organ, Pickler, Piner, Piper, Pope Prather, Pyeatt, Rebo, Regan, Rohne, Ross, Rubey, Russell (Dade), Sawyer, Schumacher, Sessinghaus Shewmaker, Sickles, Smith Snidow, Spofford, Tandy, Taylor, Thomas, Truitt, Tubbs, Vanderhoef, Vandiveer, Wade, Walmsley, Ward, Weaver, Williams (Jefferson), Wood

Senate —Anderson, Brewster, Burkhead Childers Davisson Drum, Gray, Hohenschild, Klene, Landrum McClintic, Major Marshall, Matthews Miller Morton Mott O Bannon Orchard Peers, Powers, Schweickardt, Seaber Vandiver Wells Williams —Lon V Stephens

The foregoing is a correct list of both Republicans and Democrats who supported osteopathy in the two last General Assemblies of Missouri, as shown by the Journals of the House and Senate which I desire to have printed in each medical journal in the State, and all others that are read in the State

The Physiologic Approach to Education

New York City Sept [illegible] 18[illegible]

To the Editor —Some one has said recently that there are three avenues to the approach of education the [illegible] the sociologic and the psychologic [illegible] university settlement [illegible] reform in education [illegible] their respective portions of the same great problem Who will best develop and clear the physiologic pathway?

In a generation's time the aim of education has been completely transformed In years past our boys and girls were trained for too circumscribed spheres, the one for the special trade or profession perchance selected, the other for lines far narrower, the purely domestic or social routine Today the projectors of education are satisfied with no scheme that aims not at the development of every faculty, lurking or alert There has been achieved great advance in the true direction, but there are also recognizable defects even in present day systems and possible threatenings of mistaken gains

Life has been defined as the relation of incident forces and external environment School life, educational life, follows the same law Yet too often we see environment neglected and little heed paid to coincident forces, the result being an asymmetric development of material A minor proportion of our children may be as carefully nurtured in their physical as in the mental growth, the vast majority are less fortunate Go with me into any school of average size in a cosmopolitan city, where children of all grades of society commingle They show quite alike, irrespective of social condition, too evident marks of malnutrition, of defective home hygiene, of faulty trained or neglected eye and ear, of neglected muscles, of universal errors in dress Add thereto many faulty conditions of school hygiene, of over crowded classrooms, ill lighted, worse ventilated, of dark playground or of none at all, of ill suited furniture for little aching spines and developing hips Few large schools are found in over crowded New York City, that are not over topped by many storied factories, whose noises do not aim to rise above those already hideous of city streets Is it sweetly reasonable to expect from like environment, well developed mental foundations?

What may be said of the incident forces? In all revisions of schemes of study of recent date, generous provision is made for mathematics, for language and literature, for music and drawing, for botany and biology Of what use be these, if the child acquiring them be not most familiarly acquainted with himself and the laws that regulate all his efforts to acquire and attain? In truth, the course of study providing with sufficient liberality for this first great science, physiology, is yet to be discovered Within the last two decades there was conceived the idea of its being essential to instil into growing youth a "popular knowledge of stimulants and narcotics" The intention was excellent, but its accomplishment inefficient For the purpose physiology was introduced into the school curriculum, but in so defective a manner, and with so narrow a presentation, that the only impression produced on the mind of the irreverent student, is a frivolous regard for the "liquor books" Is it justifiable that outside of the medical profession, there should be no persistent and thorough investigation of physiologic laws and no proper presentation of them? In not half a dozen of the numerous public schools of New York City, is physiology taught by a physician I presume this to be a fair average of similar conditions in other cities In the medical college of the least pretension, there is a theoretic course of two years in this subject In addition, many months of practical laboratory work are obligatory Moreover, the entire four years' college work is a continual round of emphasis and review of the fundamental physiologic problems of the first year All the wealth of clinical instruction now available to any student, is abounding with practical demonstration of physiologic laws For example, the abstruse problems of blood pressure and vasomotor mechanism are solved in every case of organic disease, the trophic nerves and their function in every case of even the superficial skin lesions Yet with all the constant iteration and reiteration of important truths, but few physicians feel qualified to aspire for the chair of physiology in their own Alma Mater Contrast the conditions cited with those encountered in the majority of our best secondary schools, where the teaching of these same important facts to minds far less prepared to receive them, is intrusted to one who has had no more than elementary training in "Science Lessons"

I am confronted with the argument that our school children are not in training for the medical profession I am no less sure that this fact itself makes it important that the necessary modicum of knowledge be presented by one familiar with its deepest bearings In other details are our incident forces sadly inefficient Too little attention is paid to the selection of proper text books covering the sciences So glaring are the errors found in instances, that within a month the medical society of a neighboring State discussed the necessity for presenting to the AMERICAN MEDICAL ASSOCIATION a petition for the official supervision of such books In pursuit of such investigation no less than seven differing publications were found, each pleading guilty to positive errors of fact, or to loose and unscientific presentation of important problems There is no work more fascinating, more interesting than that of human osteology Yet in not one text-book is there consideration given to the wonderful architectural principles demonstrated in the physiology of the skeleton In speaking of the chemistry of bone, custom is universal in calling the mineral matter found therein phosphate of lime, this is a loose bit of chemic inaccuracy, for lime is more correctly the phosphate of calcium In the chemistry of the blood many are the lapses of accurate statement In but one book have I found any attempt at satisfactory explanations of the oxyhemoglobin and its really wonderful composition and function, very many careless statements are made describing the circulatory and respiratory systems, in but one authority is it distinctly stated that the nose and not the mouth is the proper entrance to the respiratory passage In none can I find any distinction between active and passive organs of respirations, laying full stress on the value of each By one only, are the important vasomotor and tropic nerves studied Assuredly there is need of reform in this "physiologic approach" to education With the best of material, is it rational to expect an intelligent acceptance of the science within the scope of one year, and that usually a year of immaturity? Is it not worth a struggle to put within the reach of our boys and girls a scientific knowledge of the laws of life and health, to foster at least an incentive to the admonition now ages old, "know thyself?"

Examine Railway Employes' Eyes Periodically and in a Scientific Manner

CHICAGO, ILL, August 31, 1898

To the Editor —The importance of railway signals and their correct observation by employes is a matter the subject of which has been given a great deal of study by all railroad officers, to the extent that every conceivable form of signal that genius, talent and mechanism can contrive has been tried and each in turn served the period of its usefulness and relegated to the background, the cruder machine being supplanted by a more perfectly constructed one until today our railway signals are equal in construction to those produced in any country The medical profession has not kept pace with these mechanical students in their teachings of how to correctly observe these signals and thereby avoid accidents

The average railway surgeon is provided with a few crude tests as to color vision and is taught how to correctly operate them by a superior medical officer totally unfit and incapable of giving such instruction, the superior medical officer in many cases being incompetent himself to pass judgment upon the interior of an eye as viewed with an opthalmoscope, therefore, since he does not know anything about the interior of an eye as viewed with an ophthalmoscope, he is unable to ferret out the cause of the color blindness and is unable to give advice or instruction concerning it. In this regard the medical profession has not kept pace with these railway officials in this line of study.

To correctly observe a signal means to avoid the accident and is therefore of vital importance to all railroads. Vast sums have been expended by railroad officials to attain this success in the perfection of their various signal contrivances. Why, then, should not the medical profession teach the railway men the proper *modus operandi* to be pursued in correctly observing them.

The average railway surgeon is provided with a few skeins of yarn and taught that if the employe can not ferret out the various colors, but confuses them, he is color blind and must be rejected by the railroad officer examining him. Now these skeins are all right in their place, but there is a difference sometimes in the luminosity of these colors and in the wave lengths of the ethereal vibrations producing them giving to the color a different hue when mixed with other colors and thereby causing the employe examined to be rejected when the color blindness is only temporary and apparent and no pathologic condition present to produce it, and blindness which could not be again produced. Again, very many railway men have learned that they confuse red and green and that they must upon examination call red green. Here the man has a pathologic lesion discoverable, it may be, only by the aid of the ophthalmoscope or by an accurate mapping out of the color field by the perimeter, which few if any of the surgeons have, and which is equally important with color blindness as to lesions producing it.

No man is capable of judging an employe's color perception who can not correctly survey the fundus, noting the probable cause producing it or map out his color field or make the various tests for spinal cord or brain lesions that might produce it. Very many eyes are rejected because they can not read 20/20 (that is see at 20 feet what they should see at 20 feet), all this because the medical examiner does not know the healthy organ when he sees it and does not know, that it is, perchance, simply a slight refractive error easily remedied by the proper refractive correction. Moreover, very many diseases prevalent among railway men, such as syphilis, rheumatism, Bright's disease, tuberculosis, etc., not sufficiently marked to lower acuity of vision at the time of examination, which later produces total blindness in the organ, go by undiscovered by the railway surgeon and a grave accident results. The railway surgeon should be correctly instructed concerning positive and negative scotomas, how detected, and their signifiance as to the correct observation of signals. I said in a recent paper published in the *Railway Age*, that, "If any man can not read 20/20, that is, see at 20 feet what he should see at 20 feet, which for practical purposes is infinity, he should not be at the head of a passenger train freighted with human lives." If he can not read 20/20 and his fundus is normal, why not give him the proper correction and let him wear it. Periodic examinations by competent oculists would remedy the defects, if refractive, and ferret out the poor sighted employes, and, where possible, correct their vision by properly adjusted glasses.

I am aware that railroad officials are loath to part with trusty employes and for that reason keep their old employes in the most hazardous positions. This is as it should be, save that if upon frequent examinations it becomes a known fact that the particular employe has diminished acuity of vision from any source unremediable he should be substituted by a younger but equally trusty employe, whose acuity of vision can be made perfect or nearly so. I believe that the older employe with lessened acuity of vision should be given the less important positions where signals are not observed.

Another condition is that of hemeralopia and nyctalopia night and day blindness, where an individual may see perfectly for twelve hours out of the twenty-four and indistinctly the other twelve. These symptoms are manifested in certain retinal affections, and discoverable, it may be, only by the aid of an ophthalmoscope the individual, if being examined, declaring that he sees perfectly, while the ophthalmoscope shows an acute or chronic, traumatic or albuminuric retinitis or retinitis pigmentosa. Another condition is that of tobacco amblyopia, sooner or later to affect the optic nerve by causing atrophy of it, scotoma, contracted field, color blindness and finally total blindness of the eye. The same condition is possible by imbibing too freely in spirituous beverages. Who is to pass judgment on this condition? No one but the skilled physician who is able to survey the interior of an eye.

Very many other conditions might be cited, prevalent among railroad men, which lower the acuity of vision, and which therefore necessitate a periodic examination of all employes' eyes by competent oculists, especially employes having to do with signals. Every railroad should have a competent oculist with enough assistants to correctly examine, periodically, both subjectively and by means of an ophthalmoscope, the eyes of all employes having to do with signals. This will, if properly executed, lessen the railway accidents the first year by one half and relieve the railway surgeons of one of the supposed functions of their respective offices. I am aware that all railways employ oculists in name, but not in fact, their supposed function being to examine the fundus of all feigners in railway accidents and pronounce them healthy eyes and to be a general consultant in case the railway surgeon accidentally suspects some fundus lesion.

Recently in a medical journal I noted an expression from a railway surgeon of note in which he claims that the employe's character is of vastly more account to the railway employing him than is his eyesight. In my judgment both should be good and no employe placed who can not demonstrate that he has both good character and good eyes. A law should be passed in every State in the Union compelling the railway companies to periodically examine all their employes having to do with signals and especially those in the train service. This would prove no injustice to any, but would be a boon to humanity in the saving of lives and a saving to the railroads in thousands of dollars spent annually on accidents.

JNO. RANSOM HAMILL, M.D.,
Ass't Surgeon Illinois Charitable Eye and Ear Infirmary.

The Association and the Colleges

LOUISVILLE, KY., Sept. 5, 1898.

To the Editor:—In the JOURNAL of September 3, page 537, Dr. T. J. Happel, ex-vice-president of the AMERICAN MEDICAL ASSOCIATION, says: "After carefully reading the notices sent out by Dr. Wm. B. Atkinson to the deans of the several colleges in the United States, I am satisfied that the ASSOCIATION has attempted to reach a point which it should attain in an unconstitutional manner. Had this point of order been made against the resolution at the time it was offered, as the presiding officer of the ASSOCIATION on that day, I would have decided the point well taken, and have ruled it out of order."

Dr. Happel presided on Wednesday at the time the resolutions were offered. He referred them to the business committee. On Thursday the business committee recommended their adoption, Dr. Happel, again presiding, put the question and decided the resolutions unanimously adopted. He was then the only person authorized to decide. He was at that time under solemn obligation to execute all the provisions of the constitution of the AMERICAN MEDICAL ASSOCIATION. He decided then as an officer clothed with full power.

It is now about three months since he ceased to be an officer and it is an unheard *of proceeding for him to undertake, after* he has passed out of office, to decide that his conduct in office was *irregular, unconstitutional* and void Does not Dr Happel know that ignorance of the law can never be pleaded as an excuse for its violation?

The resolutions are an ordinance of the Association, and not a constitutional amendment, and, whilst they affect the qualifications of certain persons holding membership, they are, in fact, intended merely as an addition to the by laws

The constitution says of delegates, and other members, that they "shall continue such so long as they remain in *good standing* in the body from which they were sent as delegates, and *comply with the requirements of the by laws* of the Association," and of the permanent members, "so long as they shall *continue to conform to its regulations*" The constitution, therefore, decides that the provisions of the by laws are to determine the qualifications of membership, or rather, the conditions upon which membership may be continued See Art ix of the by laws, entitled "Conditions Excluding Representation"

The resolution to which Dr Happel makes reference does not alter or amend the constitution of the Association It amends Art ix of the by laws by adding to the specifications of conduct which shall exclude from representation

Article viii of the by laws formerly contained this paragraph (Transactions, Vol xxxi, page 191) "It shall be the duty of every member of the Association, who learns that any existing medical school departs from the published conditions of graduation, to report the fact at the annual meetings, and, on proof of the fact, such school shall be deprived of its representation in this body" The by laws, in relation to the conditions excluding representation, have been amended so often that it would require a large octavo volume to contain all of them The only rule with which I am familiar, concerning amendments to the by laws, is that set forth in the first Article, which says "the order of business shall, at all times, be subject to the vote of three fourths of all the members in attendance"

I am sure the Association will enforce the provisions of the resolution, it must do so or stultify itself The technical quibble about attempting to make the resolution appear as an amendment to the constitution is both unreasonable and absurd

The profession of medicine can not have more than one standard of qualification The minimum curriculum of the College Association, which has been unanimously adopted by the American Medical Association, is the lowest that can be accepted of any candidate for admission to the regular medical profession in the United States The Degree of Doctor of Medicine must be of equal dignity and effect, whether conferred in the North or the South, the East or the West, there can be but one standard

Dudley S Reynolds

An Osteopathy Assertion

Chicago, Sept 4, 1898

To the Editor —The recently issued circular of the Chicago College of "Osteopathy" contains the assertion that the "orificialist" E H Pratt (one of the faculty) is a member of the Chicago Academy of Medicine He has never been a member nor (as the Chicago Academy of Medicine is affiliated with the American Medical Association) would he be eligible

Jas G Kiernan, M D, Secretary

NECROLOGY

James K Hogan, M D, Long Island College Hospital, N Y, 1888, died at his home in New York City, September 3, aged 42 years He was a native of Ireland and a graduate of Queen's College, Cork, before he arrived in this country Two small children are his survivors

George McCreery, M D, Bellevue Hospital Medical College, 1877, died on board the transport *Catania* and was buried at sea He was appointed an Assistant Surgeon, U S Army, and attained the rank of Major at the beginning of the present war

Dr L v Dittel, in his 83d year The Vienna school loses in him one of its most brilliant minds, and the science of urology one of its modern founders His name is, perhaps, best known by one of his minor achievements, the elastic ligature of hemorrhoidal nodules

Dr G Zancarol, at Alexandria, Egypt A prominent physician among the European colonies in Egypt and writer on medical and surgical subjects and international hygiene

Dr Bonsdorff, aged 83 Formerly professor of anatomy at Helsingfors

William H Bennett, M D, N Y University Medical College, 1870, died at his home in Brooklyn, N Y, September 1, aged 54 years ——J P Fryer, M D Ypsilanti, Mich, August 26 ——F S Hilbish, M D, Fremont, Ohio, August 25, aged 56 years ——W B Scales, M D, Sedalia, Mo, August 27, aged 57 years ——John Stearns, M D, Washington, D C, August 26, acting U S Surgeon Fourth Mass Heavy Artillery, during the civil war ——Richard Townsend, M D, Philadelphia, August 28 ——William Vannuys, M D, Anderson, Ind, Rush Medical College, 1855, August 28 ——J M Wilkinson, M D, Dover, Del, August 25, aged 48 years

PUBLIC HEALTH

Reduction of Typhoid Fever in the French Army —One of the chief factors in the reduction of the number of cases of typhoid in the French army is the regulation forbidding the men frequenting saloons, cafés, etc, where non sterilized water is used The consequence is that the proprietors vie with each other in the work of sterilization

Unlowered Death Rate in Diphtheria —The discussion following Professor Kassowitz's arraignment of antitoxin treatment and the Klebs Loeffler bacillus, mentioned in the Journal, page 257, lasted four weeks and packed the rooms of the Vienna k k Medical Association to the doors, in spite of the midsummer heat, at each session In conclusion Kassowitz stated that he had accomplished his purpose if he had called attention to the fact that antitoxin treatment is not a *res adjudicata*, but is still on trial, and required scientific weighing of actual facts, instead of blind laudation

The Mosquito and Leprosy —The mosquito is now credited with the transmission, not only of malarial infection but of leprosy Prof Sommer of Buenos Ayres in an article on "Leprosy in the Argentine Republic" (*Semana Médica*, June 23), notes that in hot countries leprosy is more frequent in localities where there is much water and hence larger numbers of mosquitoes He considers this the explanation of the prevalence of leprosy among fish eating populations, which used to be ascribed to the fish Kaposi reported at the recent Lepra Congress the case of a tourist on a steamer passing through the Suez Canal who was stung on the finger by a mosquito and a leproma developed at the spot

How to Exterminate Mosquitoes —An almost imperceptible amount of potassium permanganate—1 to 1500—is fatal to the mosquito, according to the *Public Health Journal* By scattering the crystals here and there, a handful of potassium permanganate will oxidize a ten acre marsh and kill all the mosquitoes and their embryos in it, thus freeing man from the pest for thirty days *Janus* for August states that an oil medium is better than an aqueous for insecticides, as the oil works its way into inaccessible crevices Another communication de scribes the peculiar behavior and evident epidemic among ants, in the course of the bubonic plague in India

Acclimatization in the Tropics —Dr Koerfer proclaims in the *Deutsche Med Woch* of July 7, that if Europeans would leave their pork fat, their meats and their alcohol at home with their furs and heating stoves, when they go to reside in the tropics, they would avoid all the disturbances that are erroneously ascribed to the climate, but which are, in fact, only due to the failure to conform to natural laws He considers that nature makes the food conform to the climatic conditions—from the fish oil polar zone, through the pork fat temperate zone to the olive oil and vegetable tropic zone He writes from an experience of several years in the tropics, and adds that he never saw a single case of sunstroke nor impending symptoms, and that he felt better subjectively when actively employed than when lounging, no matter how high the temperature

***Prophylaxis of Tuberculosis** —One of the Paris dailies observed* in reference to the Tuberculosis Congress "The scientists now tell us that thousands of lives will be saved every year if we will only spit in our pockets" It has been suggested that the "family plan" might prove as beneficial for tuberculous children as it has proved for the mildly insane It would be cheaper to board children in families in the country than to provide special sanatoria for them, of course restricting the plan to children with ganglionary or osseous tuberculosis, not open lesions Andvord considers it more than probable that the seeds of tuberculosis are implanted in early childhood in an overwhelming majority of the cases that develop later, especially in children Hence true prophylaxis is to guard the children from infection, and cure at once all scrofulous and catarrhal symptoms and tendency to a contracted chest, cough and rapid pulse

Military Status of Medical Officers —"The medical officer should be the commander in chief in campaigns in hot countries" are the concluding words of an article by Professor Le Dantec of the French navy, in the *Arch Clin de Bordeaux* for July "The real enemy is the climate, and none but natives or negroes should occupy the lowlands White troops should never be called upon for garrison duty or work in hot countries except in elevated regions" He quotes the popular sayings "In the tropics, every white man who tills the soil digs his own grave' and the Madagascar boast, "Our country need not fear invasion, as it is defended by General Tazo, the fever" In the northern hemisphere, he adds, there is no country exempt from paludism south of the sixtieth parallel, while in the southern hemisphere all the countries south of the thirtieth parallel are free from it, i e persons coming to reside there are not affected with intermittent fever, including La Plata Patagonia, New Zealand and even New Caledonia While stationed at Bourail, the chief agricultural center of the French colony in New Caledonia, he had no call for a single grain of quinin during the entire year He considers the terms paludism, tellurism, malarial infection, etc, unscientific and suggests "Laveran's disease' as the most appropriate term

The Royal Tuberculosis Commission Report —The recent report of the British Committee on tuberculosis is to be regarded as an epoch making document which will undoubtedly lead up to valuable life saving legislation in the near future This is the third commission within the last ten years to inquire into the subject The last was the Royal Commission of 1890 which established the foundations of our knowledge as to the relation between tuberculosis in man and the means by which it is imported through the flesh and milk of tubercular animals The chief recommendation to secure the purity of milk is that notification of every disease in the udder should be made compulsory, under penalty on the owners of all cows and this is followed by a recommendation that local authorities should be invested with powers of systematic inspection and analysis Medical officers should also be empowered to suspend the sale of milk of any suspected cow and to prevent the sale of milk from a cow with a diseased udder Then come important recommendations with regard to the regulations of cow sheds and byres Certain leading principles are laid down under this heading, including the provision of proper water supply and drainage facilities, of a minimum cubic space of from 600 feet to 800 feet and a minimum floor space of 50 feet for each adult beast and of sufficient light and ventilation, the last named being the most essential requirements These requirements are directed chiefly to dairy accommodation in populous districts, the conditions in rural districts vary so widely with local circumstances that no minimum cubic space can be specified, the one end to be kept in view being the maintenance of reasonable ventilation without draughts All these precautions, however, are recognized to be but temporary and uncertain palliatives so long as no attempt is made to eliminate the disease from the animals themselves, and this part of the inquiry may therefore be regarded as the groundwork of the whole The commission is of the opinion that if the tuberculin test is skilfully applied and the animals which react are carefully separated from the healthy ones, the disease may be reduced to small proportions in a limited time and at a moderate expense The precedent set them by the Danish Government forms the basis of their recommendation that funds should be placed at the disposal of the Board of Agriculture for the preparation of commercial tuberculin, and that stock owers should be encouraged to test their animals by the gratuitous offer of a veterinary surgeon to see the test applied This offer is, however, to be conditional on the owners undertaking to isolate reacting animals from healthy ones and to keep their stock under satisfactory sanitary conditions, especially in *regard to air space, light and ventilation In Denmark* the results of the government's experiment have been most encouraging, and if similar results are obtained in this country we may hope to see our agriculturists gradually eliminating the scourge of tuberculosis from their herds and enabling us to look forward to the day when we may be able to check the spread of the disease among mankind —*The Sanitary Record*

SOCIETY NEWS

Tri State Medical Society —The tenth annual meeting of the Tri State Medical Society of Alabama, Georgia and Tennessee will be held at Birmingham Ala, Tuesday, Wednesday and Thursday, Oct 25, 26 and 27, 1898 Frank Trester Smith M D secretary

MISCELLANY

A New Midwife Institute —A midwife institute is to be erected at St Petersburg on an enormous scale to cost nearly two million roubles the present small institute for the purp [illegible] been found inadequate

Congress of Hypnotism —The second international [illegible] of experimental hypnotism is to meet at Paris in August [illegible] immediately after the International Medical Congress [illegible] already well under way, with Dumontpallier president and Berillon secretary general

New Publications —Two new candidates for [illegible] medical profession are the *South African [illegible]* Cape Town which began publication July 15 [illegible] *Digest and Formulary* published at [illegible] at $1 a year, the August issue being Vol [illegible]

Maggots in the Ear —[illegible] woman affected with [illegible] pain One-twenty [illegible] a couple more emerged from the depths when air was blown into the tube —*Deutsch Med Woch*, July 7

Syphilis in Physicians —Brandis has collected ten cases of syphilis in physicians, all infected professionally in the fingers, and all extremely violent cases, only yielding to prolonged and repeated treatment The diagnosis was made very late in each case —*Deutsch Med Woch*, No 21

To Avert Collisions in Fogs —The catastrophe to *La Bourgogne* recalls the suggestion made a while ago by a French physician, that every swift ocean liner should have among its crew a couple of men born blind, as their phenomenally acute hearing would detect the approach of a vessel even in the densest fog

Preservation of Cholera and Typhus Vaccin —Pfeiffer and Marx have established that cholera and typhus vaccin for preventive inoculations can be kept for a period of at least four to ten weeks by the addition of 0 5 per cent phenol, and that the effect of high temperatures, as high as 37 degrees C, does not impair their efficiency —*Deutsche Med Woch*, August 4

Pyonephrosis of Ectopic Kidney —A pyonephrosis of an ectopic kidney in the tissues of the mesentery of the small intestine is the unique observation reported by Dartigues in the *Presse Méd* of June 29, diagnosed a hydatic cyst of the liver Severe hemorrhage followed ablation, controlled by a Mikulicz packed with gauze Patient died following day Tumor first noticed forty years before

Merited Honors —The University of Michigan has made Dr A Jacobi of New York an LL D The University of Edinburgh on July 30 conferred the same degree upon Drs Henry P Bowditch of Boston, William Osler of Baltimore and Roddick of Montreal The last named was President of the British Medical Association which met during the summer of last year, the other two were delegates in attendance

Osteomata of the Frontal Sinuses —Nine deaths followed surgical intervention in the twenty cases on record A S Tauber describes another case in which he removed three from a 32 year old patient, which had developed subsequent to a traumatic injury above the left eye and caused pronounced ocular disturbances He found several polypus growths in the mucosa with the osteomata, one still growing and two dead —*Cbl f Chir*, July 23

Veiling Taste of Boiled Milk —According to Professor Gartner of Vienna the cooked taste of boiled milk can be prevented by keeping it from the contact with the air He accomplishes this by dropping a small piece of paraffin into the milk, which melts at 70 degrees C and spreads out in a thin layer on top of the milk, allowing the escape of gases, while preventing the ingress of air, and forming an air tight, hard cover over the top as it cools —*Munich Med Woch*, July 19

Peculiar Parasitism —Flouquet describes the case of a woman of 53, who never had had a serious illness, but complained of continuous pain in the stomach, with frequent acute exacerbations only relieved by drinking cold water, and terminating by the vomiting of certain vegetable fibers and grains presenting the characteristics of phanerogamia angiosperma growing deprived of light —*Journ des Sc Méd de Lille*, July 16

Bone Elimination per Urethra —The elimination of fragments of bone through the urinary passages is always consecutive to a suppurative ostitic process or traumatism, in some cases after an interval of many years G B Schmidt reports two personal cases and reviews the eleven on record All but two were men In some cases the bone passed through comparatively rapidly, in others it became encrusted and required an operation —*Munich Med Woch*, July 10

Etiology of Caseous Pneumonia.—Auclair has demonstrated that the lesions in this affection are produced by the toxins of the Koch bacillus alone He states that tuberculous pneumonia in all its stages—red hepatisation, gray hepatisation, caseous degeneration—is the work of the Koch bacillus and not of any superadded microbe It is produced by the action of the toxin secreted by the bacillus of human tuberculosis ethero bacilli and also chloroformo bacilli, whose specific action he is the first to establish —*Progrès Méd*, July 23

Gen Leonard Wood and lately Colonel of the Rough Riders, before the war a physician, now military governor of Santiago, is proving himself a sanitarian of no mean capacity He causes the streets of the captured city to be daily flushed by means of a fire engine and gives a wage of a dollar per diem to each sweeper of the streets These "American notions" are not much relished but simply tolerated, inasmuch as appetites are keener for the government rations and labor is now becoming as good a fad as golf

Sterilized Milk for the Infants of Brooklyn —Ex Commissioner of Health Nathan Straus of Manhattan is to give Brooklyn the benefit of his Manhattan plant for the supply of Pasteurized milk He writes to the Board of Health as follows "Although my twelve milk depots in New York City tax my laboratory to very nearly its full capacity, I have decided to place at your disposal, to be distributed as heretofore in Brooklyn, 1000 bottles per day, and as many more as the capacity of my laboratory will permit, until the heated term is over I am ready to begin supplying you at a moment's notice, and it will give me pleasure to have the distribution begun at the earliest hour the necessary arrangements will allow"

Partial Thyroidectomy, according to a report by Booth (*Medical Record*, August 13), in eight cases of Graves' disease cured five One died, and in one there has been no change, while there has been improvement in one where the operation has only been performed six months and a greater improvement with a possible cure may be expected His conclusions are: 1 Cases may be entirely cured by operative measures 2 Pathologic and clinical evidence is in support of the view that the symptom complex is the expression of a primary neurosis multiplied by a secondary glandular intoxication 3 While the ultimate cause of the disease of the gland is still a matter of speculation and a mortality of 7 per cent after operation is reported, we can not justly recommend it as a routine plan of treatment 4 Sudden death may occur in or soon after operation, and has not as yet received a satisfactory explanation

A Lying in Hospital in Moscow, according to Dr F O Donahue (Transactions of the N Y State Medical Association, Vol xiv, 1897), affords accommodations for 4,006 patients This particular institution is for the almost exclusive use of parturients whose children are born out of wedlock In Russia, criminal abortion is unknown, notwithstanding that a high degree of morality does not exist in the sexual relations There, although the regular soldiers are not allowed to marry, the government takes care of their children Foundling hospitals bind out the children to foster parents and the mother in each instance is allowed occasional communication with her child Thus does Russia look after her population, in marked contrast with France, where there has been no increased census during the past decade, and yet no claim for the latter country is urged on the score of morals Practically, therefore, Russia is wiser in her generation

Protection Afforded by the Organs —The *Presse Méd* of June 15 contains the report of experiments by H Roger, who injected 163 rabbits and 16 guinea pigs with various microbes at five different points in the circulation, to study the protection afforded by the liver and other organs He found that the microbes are always arrested in the first capillary network they encounter and that the liver disposes of the anthrax, staphylococcus aureus and oidii introduced into the portal vein, so that they disappear and none can be found after a brief interval, but the reverse is the case with streptococcus and coli bacillus which seem to find the liver a favorable soil and flourish in it, producing extensive lesions The lung opposes a feeble resistance to the anthrax staphylococcus aureus and oidii, but has a marked bactericidal effect on the streptococcus, although not beyond the limit of neutralizing a fatal dose The kidney disposes of the oidium albicans

Forcible Reduction of Deformed Spine—According to Calot this causes such laceration and gaps in the bones and tissues that many think repair would be difficult even in healthy persons, and that it must be adding fuel to the fire in diseased conditions L Wullstein has devised an apparatus that accomplishes the same ultimate results by a slow gradual process instead of Calot's one startling performance The spine is gradually pulled straight by continuous traction, the patient reclining suspended in an iron frame bed with a dynamometer to regulate the traction The face, lower jaw, arms, abdomen, chest and some other parts are left free Radiographs taken before, during and after treatment show the remarkable beneficial action of the various factors employed in the reduction The apparatus is described in full and illustrated in the *Cbl f Chir*, July 9

Suprasymphysar Implantation—Mikulicz recently performed the operation of suprasymphysar implantation of the urethra and penis in the bladder on a young man whose anal and perineal region had been shot away with the upper part of the scrotum The urethra was entirely destroyed above the end of the pars bulbosa The roots of the corpora cavernosa of the penis were severed and the dorsal artery and vein tied, while the corpora cavernosa urethræ was detached whole and lifted into a channel cut for it in the edge of the pubis The bladder was then opened and the urethra in the pars bulbosa sewed into the bladder with a wire suture, and a catheter introduced The patient recovered rapidly He can now—twelve months later—retain his urine two hours, and urinate in a stream A fistula in the perineum is not yet entirely healed, evidently there is some small sequester still left from the original traumatism Otherwise the results are so satisfactory that Mikulicz recommends the method in case of extensive traumatic destruction or neoplasms—*Cbl f Chir*, July 20

Corks and Labels—Eisen (*Journal of Applied Microscopy*, July) uses paraffin to counteract the destruction of labels and corks After the labels have been written and have become perfectly dry, he dips them in melted paraffin long enough to allow the paraffin to soak through and make the paper semi transparent—a few seconds to a minute Taking the label out, the paraffin is drained off and in a few seconds has hardened sufficiently to allow the label to be placed in the bottle with the alcoholic specimens, without deteriorating in color or composition The paraffin prevents the writing being tampered with or other writing added In the case of corks, he places them in the boiling or melted paraffin for a few minutes, when the paraffin will fill up the pores In placing the cork in the bottle he places a string at one side to allow the air to escape, or the cork will not stay in the bottle The corks should be perfectly dry and new After placing the name and number of the specimen on a label, which is stuck on the cork by a couple of pins, he dips the neck of the bottle and cork in the paraffin, hermetically sealing it Bottles treated thus do not require refilling, as the alcohol does not evaporate and the labels remain clean and neat

Rachitic Deformities.—Reginald H Sayre (*Pediatrics*, August 15) believes cod liver oil of benefit in the treatment, except possibly in hot weather He has found phosphorus together with correction in diet, advantageous, and administers it in the form of the elixir of the "National Formulary, devised by Dr Chas Rice of Bellevue He finds that children a year old can take 1/100 grain of phosphorus three times a day with no bad results, and in somewhat older children he has given a grain three times a day with great benefit "Small children with ricketts ought to be kept in the recumbent position and receive daily massage, as the soft tissues of their bodies are as much below the normal tonicity as are their bones In many of these cases slight antero posterior or lateral curvatures of the spine can be detected, and in such cases I know of nothing so useful as the wire cuirass It is far better than confinement in bed, as it permits the child to be carried out doors for fresh air and sunshine—two great aids in cases of malnutrition, whose effect seems to be often overlooked, while too much importance is attached to drugs "

Surgery of the Brain—Baudet reports a case of supposed tumor, patient comatose, operated upon and no lesion found, but the intervention relieved the patient and cured the epileptic attacks, paralysis, etc He reviews four similar cases in literature *Rev Int de Therap*, No 3 Thoel notes a case of pure hyperthermia at 40 degrees C for forty five days, in patient trephined for old fracture of the skull, causing epilepsy He considers it the result of direct irritation of the corpus striatum by the operation, as the latest investigations seem to indicate that the corpus striatum is the chief heat center *Mitt a den Grenzb*, ii, No 1 Braun relates a case of epilepsy cured by extirpation of the center for the left hand, after cyst had been removed and the skull scraped without curing it The thirty cases on record treated by ablation of a motor center have resulted in eight failures, nine improvements and thirteen cured—three over three years—*Deutsche Ztschr f Chir*, Vol xlviii, No 3 Abstracts in *Cbl f Chir*, July 23, and *Munich Med Woch*

Dural Infusion—Jacob (of Leyden's clinic) considers himself justified by the results of his experimental work on dogs, in recommending the utilization of lumbar puncture for direct therapeutic applications in cerebro spinal diseases in man, when the method is perfected by further research No reaction followed injections of 50 c c of ¼ to 1½ per cent carbolized water, nor subarachnoid injections of 35 c c of 1½ per cent solution of chloral hydrate, but severe transient symptoms of endocranial pressure and of intoxication followed the injection of 25 c c of a 4 per cent solution of potassium iodid, which lasted from ten to twenty four hours Pain and agitation also followed the injection of phys solution, although as much as 75 c c of a 1 per cent solution of sodium chlorid could be injected without reaction The iodin is rapidly absorbed and retained by the brain matter and spinal cord, not appearing in the urine until long after the usual interval when administered *per os* The fact that a small amount of a non irritating fluid injected is nearly all absorbed, while a large amount—50 c c—is not, suggests the existence of a system of valves in the subarachnoid spaces His experiments also confirm the theory of the incompressibility of the cerebral substance, the symptoms ascribed to pressure from an increased amount of cephalo rachidian fluid being really due to anæmia caused by the pressure of the fluid on the artery—*Gaz d Osp e d Clin*, from *Berlin Klin Woch*, 21 and 22.

Anomalies of the Bladder From Ovarian Tumors and Fibro Myoma—O Bloch contributes a comprehensive study of this subject to the *Nordisk Med Ark*, 1898, No 2, including a study of the lesions occurring in such cases during laparotomies He has found the bladder abnormally shaped in five out of his [illegible] laparotomies, and has collected 33 other cases of lesions due to the abnormal shapes, which he groups as the 'leaf shape,' the 'hour glass,' the "triangle perpendicular or inclined and the "sausage' The bladder in most of these cases [illegible] only extended up to the umbilicus but its appearance and texture were so altered that its identity was never suspected Careful examination beforehand vigilant attention during the operation, bearing in mind the 38 cases of anomalies recorded and that 14 out of the 33 injured died, the cautious [illegible] tion of a hard catheter, or better still, the injection of boricated water through a soft catheter in case of doubt, will aid in the diagnosis and forestall injury If, when the peritoneum is opened, it does not look normal, leave that point and incise elsewhere Lunggren reports in another issue the case of a twelve year old boy, upon whom he operated on account of a vanishing and recurring tumor, causing intense pain at times The tumor was found to be a second normal bladder, but with no communication with the first An anastomosis was made between the two and all disturbances ceased

Cancer of the Breast —Warren (*Boston Med and Surg Jour* , August 15) tabulates 72 cases covering a period of fifteen years, of which 21 are known to be alive at the present time and 38 dead Of those dead, 2 were from other diseases than cancer and that long after the danger limit had passed Of the 26 living, 3 now have recurrence of the disease and 4 have had, but remain well at present His figures show that the disease is more frequently found in the upper and outer quadrant than in any other quadrant, in the upper oftener than in the lower hemisphere, and in the outer rather than in the inner hemisphere The date of recurrence could not be learned in 9 cases, but in 41 it occurred within three years in 37, between three and four years in 2, and between five and nine years in 2 Considering three years as the limit, as a gage of the success of the operation there are 17 cases Two of these are dead, "one dying, ten years after the operation of apoplexy, and one dying of sporadic cholera six years after the operation" , 3 had recurrences, from which they are at present well , one of them three years, one four years and one ten years after the operation " He considers retraction of the nipple an unreliable symptom, it being present in only 13 of the cases, and there may be extensive disease of the breast without nipple retraction The dimplings of the skin over the nodule are more significant and in marked contrast to the protrusion of the growth, in the case of a benign tumor or cyst above the surface when the patient is in the recumbent posture "

Experiments Regarding the "Setting" of Plaster of Paris —J A Belcher reports (*Treatment*) the results of experiments undertaken to determine the effects of various agents on the "setting" of plaster of Paris "Two drachms of plaster, mixed with one drachm of a 5 per cent solution of sodium chlorid, hardened in two minutes Mixed with one drachm of a 5 per cent solution of sugar, it hardened in three minutes and a half Mixed with one drachm of a 1 per cent sodium chlorid solution, it hardened in five minutes Mixed with one drachm of an 0 5 per cent sodium chlorid solution, it hardened in five minutes Mixed with one drachm of a 5 per cent calcium chlorid solution, it hardened in six minutes and a half Mixed with one drachm of tap water, it hardened in nine minutes Mixed with one drachm of distilled water, it hardened in nine minutes Mixed with one drachm of saturated solution of sodium chlorid, it hardened in eighteen minutes Mixed with one drachm of a 5 per cent solution of glycerin in distilled water, it hardened in nineteen minutes Mixed with one drachm of a 5 per cent solution of white of egg in distilled water, it hardened in twenty minutes Mixed with one drachm of a 10 per cent solution of white of egg in distilled water, it hardened in twenty five minutes Mixed with one drachm of a 10 per cent solution of glycerin in distilled water, it hardened in thirty five minutes Mixed with one drachm of a 25 per cent solution of glycerin in distilled water, it hardened in sixty minutes" The figures tell, says Belcher, their own tale, and show that where it is of importance to make plaster of Paris set rapidly it should be mixed with a five per cent solution of common salt and this may be made roughly by adding a tablespoonful of salt to a pint of water —*Scientific American*, August 13

Gloves in Surgery —McBurney (*Annals of Surgery* for July) gives a detailed report of the results which have followed in his surgical work since his adoption of the use of india rubber gloves in all operations, last October The fact that the glove can be boiled and so made absolutely sterile is a matter of especial moment, and being non absorbent, they remain sterile throughout the operation By their use, no matter to what previous use the operator's hands may have been put, he may begin his operation without dread that they may cause infection, and may even operate with a suppurating lesion on his own hand, with impunity The rubber gloves add greatly to the operator's comfort, and avoid loss of time and the annoyance caused by a prolonged effort to sterilize his hands He simply washes his hands in soap and water and puts on his sterilized gloves, and when he removes his gloves the hands are perfectly clean and soft and the nails free from any discoloration, while no cracking occurs By them there is always protection against infection The operator soon accustoms himself to the use of the gloves, being able to thread needles, handle instruments, tie ligatures, as well and rapidly as without them As to the sense of touch, he does not find it blunted by the use of gloves Probably the fact that the hands are never hard and callous or roughened by irritating disinfectants accounts somewhat for this acute sense of touch He boils the gloves fifteen minutes in a 1 per cent soda solution, after first washing them thoroughly in soap and hot water, to which a little aqua ammoniæ has been added From the boiling solution they are removed by sterilized forceps and placed on a sterilized towel, which is then folded over them and not opened until the individual who wishes to wear the gloves is ready to put them on A fresh pair is afforded for the operator, assistants and nurses in every operation If the hands are rubbed with dry, sterilized starch, gloves damp in the interior, can be quite easily drawn on, as can wet gloves, if the hands are moistened with glycerin The inexpensiveness of the gloves is a favorable factor, although they last from four to six weeks under daily operating (*Vide* JOURNAL for November 1897, p 1060, March 19, 1898, p 672, June 25, 1898, p 1522)

Legal Restraint of Marriages —Russell recently presented "A Plea for Posterity," before the Washington County (Pa) Medical Society (*Phil Med Jour* , August 27), a paper in which he cites statistics of many present sociologic conditions and makes a plea for legal restraint of marriage among certain classes He says "Some would deny the right of existence, claiming that this right has been forfeited by the inferior mental, moral, or physical status of himself or his ancestors As the existing order of things involves the visiting of the father's sins upon the children, even the most conservative must admit that the *defective has no right, either natural, moral, or legal, to produce a posterity cursed with his affliction, to be a danger and a burden to your posterity and mine* There are, however other fountains feeding this stream of corruption, and we can never hope to stay the tide until they are controlled through heredity itself, by *denying* to the defective the right to propagate his tainted species These founts are alcoholism syphilis, tuberculosis, epilepsy, insanity, and gonorrhea " He then considers these several "founts" in detail and concludes with a bill prepared by him for the Legislature of Pennsylvania, with a view to securing such State laws as will prevent the issuing of a marriage license to any person "contemplating marriage unless he or she shall have received from the persons so appointed a certificate setting forth that such applicants are free from the following diseases, any of which shall be deemed sufficient cause for refusing a license Syphilis, gonorrhea, dipsomania, hereditary insanity, true insanity, or insanity resulting from vice, epilepsy, hereditary consumption or tuberculosis " He says that the State of Texas already prohibits the marriage of epileptics , Massachusetts the epileptic, alcoholic and syphilitic, while Ohio has a similar law to the one proposed, and the same bill has been introduced in the Maryland Legislature

Sense of Feeling in a Lost Limb—Dr Hervie A Dobson of Washington writes of his own experiences following an amputation of his left leg He states that the limb was amputated at the middle third of the thigh over thirty four years ago The sensation of knee, foot, heel, hollow of foot, and toes being present is stronger than in the other limb In fact, when at rest one is not conscious of any sensation in his limbs in a state of health, but in the stump the sensation is ever there, sometimes painfully so This is no hallucination, but is due to anatomic and physiologic reasons "Nerves of sensation pass out from the spinal column to every part of the surface of the body, each nerve having its own particular part to supply and each conveying to the nerve center knowledge that its terminal point is being irritated Thus, a nerve terminating in the end of the big toe, no matter where it is irritated between the nerve center and the end of the toe, will say to the nerve center, 'The end of the big toe is touched or hurt' " Just before storms, when the barometric pressure is light, the air within the tissues expands and presses on these nerve ends, causing intense pain sometimes, and there is no relief but to reamputate the limb and see that the nerves are not caught in the cicatrix It is generally the stump that perished away and becomes small that gives the most annoyance He adds, "My leg was amputated in such a position that when I stand it seems to be flexed with the foot behind me, and I have often tried to remove it from the way of persons passing and have even tried to put it out to prevent the slamming of a door behind me, and much to my surprise the door did not stop I have had many a fall in trying to walk, when springing up quickly I tried to put my foot to the floor I have seen comrades whose legs were amputated below the knee, when on crutches, try to put the foot down and so come heavily on the end of the stump As I grow older there is a sense of shortening in the leg, the foot seeming to come nearer the body If I move the muscles of the stump, as in the effort to extend the knee, a sensation of great heat occurs at once in the stump, when it may be almost frozen with cold Dry heat sometimes relieves pain in these stumps, but nothing will relieve permanently except an operation, as above stated "—*Literary Digest*

Mydrin, the New Mydriatic—Dr S Snell writes to the London *Lancet*, July 16, saying that he desires to confirm "my observations on this mydriatic in the Clinical Journal in 1895, which were, I think, the first published in this country I would like to add that I again refer to the value of mydrin in my volume on the 'Examination of the Eye' (Pentland), published this year My object in writing now is to reiterate my opinion of the efficacy of mydrin as a rapid pupil dilator without affecting the accommodation, and the effects of which quickly pass off, features marking it as specially adapted for producing mydriasis for ophthalmoscopic purposes The present price of the drug is, however, almost prohibitive of its use I understand that it still costs something like $6 25 a drachm, but of course a demand for it would soon bring about a reduction in price It is further to be desired that some firm should furnish the drug in the form of gelatin discs "

Washington

Report of the Health Officer.—The report of the Health Officer for the week ended August 27 shows the total number of deaths to have been 100, of which 66 were white and 34 colored The principal causes of death were Nervous diseases 16, circulatory 7, intestinal 6, genito urinary 8, diphtheria 2 typhoid fever 4 There were 36 cases of scarlet fever and 25 cases of diphtheria under treatment at the close of the report

To Improve the Water Supply —The last apppropriation bill included an item providing for the water supply of the District under the chief of Engineers, as follows "To enable the proper officer of the Government having charge of the Washington aqueduct and water supply to the city of Washington, to make an investigation into the feasibility and propriety of filtering the water supply of Washington, and to submit to Congress a full and detailed report thereon, and to meet all necessary expense of said investigation $3000 Said report shall be accompanied by a detailed estimate of the cost of the work required and in making the investigation, and in the preparation of this report, the Chief of Engineers, U S A shall be associated with the proper officer of the government in charge of the aqueduct as consulting engineer Chief Engineer Wilson has arranged through the Secretaries of War and State to be supplied with the history and latest information concerning the filtration systems adopted by the principal European cities The Secretary of State has called on the consuls of the prominent European cities for all material data relating to the operation of their systems of water supply The unfinished and abandoned water tunnel and new reservoir of the city is to be repaired and put in operation

To Inspect Camp Wikoff —Dr H L E Johnson, one of the Citizens' Committee has gone to Camp Wikoff, Montauk Point, L I, to inspect the sanitary conditions of the camp and the medical and commissary care of the District Volunteers

Louisville

Hospital Changes —Drs T J Poteet and G B Jenkins assumed places on the resident medical staff of the Louisville City Hospital, September 1 Dr Poteet is the second honor man from the Kentucky School of Medicine, and Dr Jenkins the first honor man from the Hospital College of Medicine Dr Sidney J Meyer, who received the first honor from the Kentucky School, refused the appointment to the Hospital to accept the position as Acting Assistant Physician in the Army Drs Ross and Forsyth are succeeded as internes Dr Ross goes to Leavenworth, Ind, and Dr Forsyth to Harrodsburg, Ky, to practice

School —The Louisville School Board at a recent meeting decided that the public schools would not begin their sessions until September 15, instead of the first Monday, on account of the extremely hot weather Last year the severest heat of the season occurred during the first sixteen days, when the thermometer showed a minimum of 93 and a maximum of 100 degrees

Smallpox —The State Board of Health has raised the quarantine of Jackson County, as all smallpox cases are under control and no new ones have developed The quarantine was raised upon the recommendation of Dr M R Gibson of that county, it having been left to his discretion by the State Board at a recent meeting

Muench —Dr Albert Muench is lying quite ill of typhoid fever at his residence in this city His assistant, Dr Allan McNally, was prostrated by the heat on the street but has again resumed his practice

Nurses —Kentucky has furnished a large number of nurses as volunteers in the Army hospital, among whom may be mentioned Misses Caroline Diehl, Marie Lustnauer Tweed, Elizabeth Hilf and Mary C Laughlin

Coroner —The Coroner of Jefferson County, Dr H M McCullough has submitted his report of inquests held in the county from January to July Total number of inquests 290 males 188, females, 102, white, 167, colored 133, deaths due to homicide 22, suicides 20, accidental drowning 16 railroad accidents, 13, accidental poisoning 4 wagon accidents 4, street-car accidents 2 sunstroke 1 lightning 1 This shows about the same proportion of deaths due to [illegible] as given by other statistics

Health Officer's Report —Health Officer Allen has [illegible] issued his yearly report which contains some interesting reading He calls attention to the ordinances which have been put in force since his incumbency among which may be mentioned the following Registration of birth and [illegible] regulating the burial of the dead, creating an embalming board to pass upon the qualifications of embalmers, regulating the sale of milk, empowering the Health Officer to abate nuisances, *giving right of way to physicians*, providing against overcrowding in boarding houses and tenements A number of recommendations are made, which, if the Board of Safety and Council will grant, will place the Health Department upon a sound footing and great good can be accomplished He requests an increase of the Health Department force, the appointment of Health Inspectors for each ward in the city, they to assume the duties of inspection now performed by the police, a veterinarian as live stock inspector, a competent chemist, a milk and food inspector, and additional clerical assistance in the health office An increase in the appropriation is asked, double of that for 1897 It is recommended that *consumption*, whooping cough and *typhoid* fever be included among the diseases which have now to be reported to the department He recommends the establishment of public baths in those districts where the poorer tenements are located Not much can be expected from city taxes for the accomplishment of this, but it is to be hoped that private philanthropy will actuate the establishment of this needed reform It is *recommended that all school children be vaccinated* annually, regardless of the presence or absence of small pox The teaching of sanitary science in the schools is recommended The public drainage is declared inadequate, and an addition to the eighty five miles of sewerage is asked for Cremation of public garbage is recommended and urged He favors an insane ward at the city hospital, which can be accomplished as soon as *the colored patients are moved to the* building now occupied as a male high school, shortly to be vacated, this insane ward to be used as a temporary detention ward for the insane or suspects

KENTUCKY SCHOOL —An injunction has been granted Drs S E Woody and C W Kelly against Dr W H Wathen, preventing him from in any way claiming he is Dean of the Kentucky School, and against Drs Sam Cochran and Arthur Boyd from claiming they are Professors in the School This disposes of the contention in regard to the mail, it being the order of court that all mail addressed to Dr S E Woody, Dean, or Dr W H Wathen, Dean, be delivered to Dr Woody

Philadelphia

PENNSYLVANIA HOSPITAL —The 147th annual report of the above hospital contains statistics of interest to all medical men, especially to those connected with institutions *of* similar scope and objects Since the foundation of the hospital in 1751, there have been admitted to beds in the wards 140,144 patients, of which number 96,369 were poor persons supported at the expense of the institution During the past year there were treated 3241 patients in, the wards and 13,535 in the out patient department The average cost per day for each in patient was $1 21, and average expense to the hospital of each out patient, $0 48 The average cost of each in patient compares most favorably with *that of many other large hospitals* in which the average expense ranges from $1 40 to $2 50 During the past year there were 23 amputations and 83 abdominal sections Herniotomy was performed 25 times In the Department for the Insane, the patients treated numbered 584, 266 men, and 318 women, 53 recovered, 30 improved, and 18 remained stationary Regarding the "causes" of insanity since the opening *of* the new hospital for insane in 1841, the report says "Of 10,888 admissions 55 per cent of the causes might be placed in the preventable *division*, and 45 per cent in the non preventable It may be affirmed of the whole number that more than 50 per cent of the admissions acquired their mental disease from some ills of life *not transmissible* and but a small proportion can be ascribed to heredity" During the past year the Hospital received in gifts, legacies, etc, the sum of $33,808 60, and in addition is advised of legacies amounting *to* $110,000 *The total* receipts for the year just closed were $453,650 45, and the total expense $398,275 87, leaving a net cash balance on hand of $55,384 58

HOSPITAL TRAINS IN VOGUE —As the result of the recent successful trip made by the city hospital train which brought home from the different army camps soldiers sick with typhoid fever, the movement has resulted in stirring up the city and State officials *Governor Hastings sanctioned* the movement and gave his support for the equipment of another train to go to the *front* and bring home those patients too ill to travel otherwise The Medico Chirurgical Hospital has also equipped a train of its own and sent physicians and nurses along, and it is believed that before many days every sick soldier will be cared for in well equipped hospitals Of those first brought home, all have improved, *some so much that they have already been* discharged cured

MORTALITY STATISTICS —For the week ending at noon, August 27, there were 429 deaths reported, a decrease of 17 over last week and an increase of 42 over the corresponding period of last year The following are some of the causes Apoplexy, 17, Bright's disease, 11, cancer, 8, cholera infantum, 19, consumption, 54, croup, 4, heart disease, 21, dysentery, 5, inanition, 17, marasmus, 36, old age, 13, suicide, 3, sunstroke, 6, uremia, 1

INFECTIOUS DISEASES —This week Diphtheria, 56 cases 18 deaths, scarlet fever, 17 cases, 2 deaths, typhoid fever, 118 cases, 9 deaths Last week Diphtheria, 45 cases, 16 deaths, scarlet fever, 10 cases, 1 death, typhoid fever, 78 cases, 8 deaths This rapid increase in typhoid fever is due to the return of the soldiers, brought to the city from army camps

PRESERVATION OF MILK —In an interview, Dr Henry Leffman, City Chemist, recently stated that there was a rapid increase in the rôle of salicylic acid as a preservative of milk and other articles of food Owing to this cause much harm is being done, as the drug is especially dangerous to children The artificial form used by brewers in the preparation of bottled beers is poisonous and should be prohibited Dr Leffman was of the opinion that prompt measures should be enacted for the suppression of the evil

"TYPHO MALARIAL" FEVER —Dr S Solis Cohen, Medical Chief of the Jefferson Medical College Hospital, states that the fever of soldier patients was being examined thoroughly in suspected cases in order to find out whether or not the cases *of typhoid fever were also infected with the plasmodium malaria* In an interview, Dr Cohen criticises the proper authorities quite severely for allowing preventable diseases to spread with such rapidity among the soldiers

DEATH FROM CHLOROFORM —As the result of a coroner's inquest upon the case of Catharine Montague, 36 years of age, who died at the Polyclinic Hospital of Philadelphia, the jury pronounced the death due to chloroform administered prior to a surgical operation

Medical and Hospital Service in Cuba —The following extracts from a report by First Lieut Guy C M Godfrey, Assistant Surgeon, U S A, will convey some idea of the difficulties *contended* with, and *the efficiency of* the medical and hospital service at the front

SANTIAGO DE CUBA, July 29, 1898

To the Surgeon General, U S Army, Washington, D C
(Through proper channels)

Sir —As commanding officer of the Hospital Corps Company of the First Division, Fifth Army Corps, I have the honor to submit the following report

This company was organized at Tampa, Fla, June 5, 1898, just two days previous to the departure of the troops of the First Division for the transports, at Port Tampa, Fla On the day of organization the strength of the company was eighteen privates *No non commissioned officer was assigned to it until* June 7, 1898, when Acting Hospital Steward McGuire reported *for duty* He was at once assigned as first sergeant of the company, which place he has held up to the present date A cook and an assistant cook, orderlies for the medical officers and a clerk were at once detailed

When the order came to move, the men of the company per formed the work necessary thereto, and the enthusiasm and *esprit du corps* with which they labored added greatly to the celerity and facility with which the task was accomplished The personnel and supplies of the division hospital, as well as the hospital company, was placed on board the transport *San tiago*, and arrived off the coast of Cuba, near Santiago, June 30, 1898 The day before landing, all of the material was brought up from the hold by the men of the company, and stored on the main deck of the ship near the forward starboard port This was done by direction of Major W W Wood, chief surgeon of this division, and proved a wise and efficient measure

We landed on June 15 at Siboney, Cuba, and pitched camp on the beach On this day thirteen of the privates of the hospital corps of the Seventy first New York Vols joined the company During the night of June 25, Acting Hospital Steward McGuire and five of the men worked all night unloading the material for the hospital, and storing it upon the beach under canvas This was done by using small boats drawn by steam launches, and, owing to the high swell, it was at times quite dangerous I remember several occasions where the men narrowly escaped injury from falling boxes

On June 26 the men were given a short drill to perfect organization Hurried preparations were made for a forward movement, and as absolutely no transportation could be obtained from the quartermaster's department, these preparations consisted principally in selecting such necessary dressings and drugs as the men could carry on their backs, and litters On June 27 the First Division moved forward, and the Hospital Company followed in rear of the Third Brigade, taking the road toward Seville Owing to the possibility of an immediate skirmish or battle, none of the medical officers rode their horses, but made pack mules of them, and carried as large a number of dressings, etc , as they could The divisions camped in columns of brigades, and the Hospital Company and division hospital pitched camp near the headquarters of the division commander On the following morning twenty men, with the steward and two medical officers, returned to Siboney, and brought up four litters, and as many medical supplies as possible, returning about 2 o'clock P M After a soaking rain the company broke camp, and was ordered to move forward two miles This they did, marching over a rocky, yet muddy road carrying the hospital supplies with them They pitched their shelter tents on the soaking ground, while the officers, who had no shelter, slept in the open air, exposed to dampness and poisoning On June 29 the company moved forward a quarter of a mile farther to a beautiful spot with the Aguadores River on one side and the Siboney road on the other Here on the 29th the division hospital was established, and here it remained all through the terrible carnage that followed On this day six wagon loads of our supplies were brought up from the beach at Siboney, and tent flies were pitched and everything arranged for the coming battle On June 30 the work of establishing the division hospital continued, and more of our supplies were brought from Siboney

On the evening of July 1, the writer rode in the direction of the firing toward El Caney, and while searching for an ambulance, rode to the extreme right and visited the firing line of the Twelfth Infantry He then returned and reported to Major Wood, who directed an ambulance to be at once sent in that direction Owing to the very small number of hospital corps men present with the division, and as the number of ambulances for the entire army was limited to three, it was impossible to expect them to convey the total number of wounded from the collecting stations to the First Division hospital It was soon apparent that the entire force of the hospital corps would have to be used to man the hospitals, but about noon Acting Hospital Steward McGuire, two litter squads and an ambulance went forward up the San Juan road As the Spanish shrapnel were bursting around the battery on El Paso hill, near the road it was not deemed prudent to take the ambulance beyond that point There it remained while the two litter squads pushed forward up the San Juan road One wounded man was found, who was not able to walk, about 400 yards before reaching the farthest crossing of the Aguadores River He was at once dressed and conveyed to the rear by a litter squad The other litter and the steward advanced about four hundred yards farther, to the east bank of the Aguadores, and there found a wounded man who could not walk At this time the Sixth and the Sixteenth Infantry were immediately in front and were making their advance toward San Juan hill It can therefore be seen that the hospital litter squad in rear was under the hottest kind of fire, and the bullets were cutting the leaves all around, but not one of these men faltered, or showed the least sign of fear

At this time the wounded were coming back in a constant stream, and such as needed stimulation or dressing were at once attended to by the roadside Many of them returned alone, others walked, supported by the arm of some comrade, while the more seriously wounded were borne upon litters of various kinds A few of those who returned had not received medical attention, but the majority of them were dressed with first-aid packages by the regimental surgeons and their hospital corps men

At about 1 P M Major Valery Havard, chief surgeon of the cavalry division, established an ambulance station on the east bank of the Aguadores near El Paso At this station many dressings were readjusted and a few patients were dressed for the first time Stimulants, medicines and dressings constituted the stock at this station, which was about a mile in advance of the First Division hospital No point farther to the front was safe from the enemy's fire The ambulances were worked constantly, and, considering their number, did remarkably well Late in the afternoon ambulances were taken forward to near the farthest crossing of the Aguadores but it was rather dangerous at all times, as the enemy kept the San Juan road enfiladed all day long It was also very dangerous on account of Spanish guerillas, who were located in trees overlooking the road Several men carrying wounded were shot, and, indeed, in a few cases the patients themselves were hit

Later in the afternoon a dressing station was established at the farthest point where the San Juan road crossed the Aguadores At this place there was a vertical bank about four feet high, beneath which was a gravel beach Here a certain amount of shelter was obtained, but bullets frequently cut through the bushes, or splashed up the water in the creek At one time it was enfiladed by Spanish sharpshooters in trees up the creek Several horses were killed here, but no patients, surgeons or attendants were injured that afternoon It was at this place on the following morning that Dr Danforth was killed Late in the afternoon several escort wagons, having carried ammunition to the front, were turned over to the writer by Lieutenant J D Miley, General Shafter's aide de camp These were taken to this station and filled with the wounded, who were transported to the First Division hospital Empty army wagons that could be found were used for this purpose, and the wounded kept coming into the hospital all night On the following morning an ambulance and two wagons were taken to the dressing station just described, and the wounded brought in, among them being Acting Assistant Surgeon Danforth, who was shot through the head Major S Q Robinson had assumed command of this station on the previous afternoon, but at this time he, with Captain W D McCaw, rejoined their regiments, and left the station in charge of Captain Paul Newgarden Major V Havard arrived later and established an ambulance station at this point, which was then comparatively safe It was customary during the battle for the writer to send litters and dressings to the front in the empty ambulances During and after the battle the men of the hospital corps company did much of the work in the First Division hospital They assisted in operations helped in applying dressings, made soup and coffee, carried patients to and from the operating tables, and acted as nurses to the wounded With but few exceptions, they worked all day, all night, all the following day, and most of the next night They were assisted by members of the bands of the regiments and by some of the hospital corps men of the regiments

During the battle the first aid work was very effective, and was done mostly by regimental surgeons and their hospital squads Many dressings were applied by the line officers, by soldiers on the firing line and in some instances by the wounded men themselves Major S Q Robinson who commanded the Aguadores dressing station on July 1, says that only about ten patients came there who had not been dressed by first aid packets Words can hardly express the appreciation which the officers and men of the line have for the first aid packets They realize now as never before the value and importance of instruction in first aid work The very small number of suppurating wounds can readily be accounted for prompt applications of these dressings

Pyramidal Bandages for Postpartum Hemorrhages — A very simple and easy method of arresting hemorrhage has been devised by E Iava, who hopes to see it generally adopted by obstetricians and midwives The uterus is first cleared of clots by compression from without After retraction the fundus is pressed downward toward the symphysis until the posterior surface is on top, which is easily accomplished in the relaxed post partum condition Linen cloths are then placed directly over the uterus in such a way that they form an inverted pyramid, pointing toward the spine, bound tight with a bandage around the body The external surface of the uterus and the nerve terminals are stimulated, while there is no chance for infection as all the manipulations are external —*Arch di Ostet e Ginec*, May

THE PUBLIC SERVICE

The Surgeon General of the Army and the American National Red Cross —Owing to the pressure of my official duties I have not heretofore felt justified in taking the time to make an explanation with reference to my attitude toward the American National Red Cross

It has been repeatedly charged in the newspapers that I am hostile to this organization and have refused to accept its assistance in the care of our sick and wounded soldiers and that as a result of this refusal there has been unnecessary suffering

These charges are without foundation, except in so far as I objected to the sending of female nurses with troops in the field engaged in active operations We have a Red Cross Hospital Corps in the army, of enlisted men whose duty it is to render first aid to the wounded upon the field of battle and to care for the sick in our division field hospitals, and I have been of the opinion that female nurses would be an incumbrance to troops during active operations, but so soon as serious sickness developed in our camps and it became necessary to treat typhoid fever cases in our field hospitals, I gladly accepted the services of trained female nurses for the division field hospitals and in our general hospitals we have employed them from the first The general testimony from the surgeons in charge of these hospitals has been that their services have been of great value Very many of these trained nurses have been obtained through the Red Cross Society for the Maintenance of Trained Nurses, Auxiliary No 3, and I desire to express my high appreciation of the valuable services rendered to the Medical Department of the Army by this organization

My attitude toward relief organization is shown by an endorsement dated May 5 upon a letter addressed by Rev Henry C McCook of Philadelphia to the President and referred to me for remark

"May 5, 1898 Respectfully returned to the Adjutant General of the Army

The plan proposed for the organization of a relief association seems to have been well considered and the object in view will commend itself to every patriotic citizen But it is a question whether the President should give special privileges to any particular organization Other prominent individuals in different parts of the country may be organizing for the same purpose One such proposition has come to me from Chicago While I approve in a general way of organization for the relief work proposed, it appears to me that it will be best not to give, in advance, exclusive privileges to any one particular organization In case of need assistance should be accepted from any organization prepared to give it"

This has been my guiding principle throughout, that relief when needed should be promptly accepted without reference to the source from which it comes The relief afforded by the National Red Cross at Siboney was promptly accepted by the surgeons on the spot, but it is evident that it was entirely inadequate to meet the emergency

A committee of the American National Red Cross Association called upon me in my office in Washington some time in advance of the landing of our troops in Santiago, making an offer of assistance I received them most courteously and advised them to use their resources in fitting up a hospital ship, telling them that a hospital ship was then being fitted up for the use of the Medical Department, but that it was not at all improbable that an emergency would arise which would overtax our resources, and that in such an event a hospital ship properly equipped, having on board a corps of doctors and nurses would be a most valuable auxiliary

Furthermore, the American National Red Cross Association has had full authority to send agents and supplies to all our camps since June 9, 1898, and if there has been any suffering for want of proper supplies they must share the responsibility with the Medical Department of the Army for such suffering

The following letter was sent by me to every chief surgeon of a department or independent army in the field on June 9, 1898

"The Secretary of War has approved of the following proposition made by the American National Red Cross Association, and the chief surgeons of army corps and divisions will co operate with the authorized agents of this Association for the purpose indicated

"'We can put any desired amount of hospital supplies—ice, malted milk, condensed milk, Mellin's food, etc —into any of the volunteer camps in a few hours Will you be kind enough to bring this letter to the attention of Secretary Alger and ask him if there is any objection to our appointing a Red Cross representative to report to the commanding officer and the chief surgeons in every camp, confer with them as to their immediate needs, and, if anything of any kind is wanting, open there a Red Cross station and send in supplies? We can do this, not in a few weeks or a few days, but in a few hours, and can furnish any quantity of any desired luxury or delicacy for hospital use We hereby tender our aid and put our organization at the War Department's service for co operation in this field'"

To show my cordial relations with the National Red Cross relief committee I venture to quote from a letter of August 11, received by me from Mr Cleveland H Dodge, chairman of the supply committee Mr Dodge says

"I want again to assure you personally, and on behalf of our committee, of our earnest desire to assist you in every possible way and to thank you for calling upon us so frankly"

In a recent letter from Mrs Winthrop Cowdin, Vice President of the Red Cross Society for Maintenance of Trained Nurses, she says

"We greatly appreciate your courtesy to us and feel most grateful to have been permitted to serve you in any way"

GEO V STERNBERG, Surgeon General, U S A

ADDRESS

ON THE PREDOMINANCE OF GERMAN INFLUENCE IN MODERN MEDICINE AND SURGERY

Address of the Chairman of the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY H GIFFORD, M D
OMAHA

That the Germans do take a disproportionately large part in the furtherance of medical science will not, I think, be questioned by those who have attempted to look up any medical subject thoroughly In one ophthalmologic monograph, by an American, which I happen to have at hand, there are quoted sixty-five papers by Germans (including Austro-Germans) as against forty-two from other nations, while in another, also by an American, but more strictly concerned in original research, of twenty-two authors quoted, twenty are Germans I do not mean to say that such figures give a fair idea of the actual share in medical progress taken by non-German nations, for a large part of such progress is the result, not of original research, in the ordinary sense of the term, but of clinical acumen and inventive talent, qualities in which the French and English speaking nations are certainly in no way inferior to the German But when one examines the solid basis of facts upon which modern medicine rests, facts dug out of Nature's storehouse by hard, patient work, the preponderance of German contributions is overwhelming In looking for an explanation of this fact it can not be claimed that it is due to any marked superiority of the German intellect In the roll call of the highest types of scientific ability, France and the English speaking nations certainly do not suffer by comparison The race which has produced Newton, Dalton, Darwin, Thompson and Edison certainly anks second to none in intellectual vigor And while not for a moment denying that Germany, too, has produced many first class scientific minds, it is plain I think, that the great bulk of work to which she owes her medical prominence is the work which the majority of well-educated, intelligent medical men in his, or any civilized country, could do if they would devote the necessary time and energy to it In other words, it is work which they would do if they only had sufficient incentive

Now, admitting that the Germans may have an special genius for painstaking accurate, detail work, he difference in the amount of their output in medicine, as compared with England or this country is ertainly far greater than any race difference will ccount for It can only be explained by the greater ncentive furnished by the German environment nd of this environment the prime factor in the stimulation of scientific research is the plan pursued in the appointment of university professors We are apt to think of the Germans as a nation of savants, but the rank and file of medical men in Germany do little if any more research work than is done by the average in this country The great part is done by the younger professors or those who hope to become such A considerable amount of first-class work is done by candidates for the doctor's degree still more by the assistants, but most of all by the privat-docenten, young men who for the best years of their lives defer matrimony and financial advancement and devote their whole energy to original work, each one knowing that with good ability, if he is industrious and sincere, he is sure to be rewarded in time by a professorship or some other important position[1] If the first position is in one of the smaller universities, the young professor, once installed, renews his work knowing that only by so doing can he hope for a call to a larger field Called from Giessen, Marburg or Erlangen to Breslau, Halle or Munich, some men find their ambition satisfied, relax their efforts and are but seldom heard from again, but a fair proportion, either from habit or love of the work, or in the hope that on the rare occasions of vacancies at Berlin or Vienna they will be the chosen ones, keep hard at work adding to the magnificent pile of German learning Of the numbers who start in the race for academic preferment, many must fall behind, but all are encouraged, at the outset, by the knowledge that the work which they do, even if it fail to be rewarded with a professorship, will be the best passport to one of the numerous positions at the head of hospitals or in public health departments, these institutions acting thus as powerful auxiliaries of the universities in the work of inciting to original research

The most important differences between Germany and America in the matter of medical appointments are the much higher standard of the Germans and the custom of their university faculties of filling vacancies from other institutions than their own Much has recently been done in this country toward elevating the standard for admission to the medical profession, but until much more is done to raise the requirements for medical professorships, anything like an approach to Germany's scientific output is entirely out of the question I think it is no exaggeration to say, leaving the smaller institutions out of the question, that in the best twenty of our medical schools more than one half of the professors, taken in the aggregate, have *secured* their positions for considerations which in Germany would hardly entitle them to the rank of privat docent To be sure, the best men as a rule, get the best places to be had in the city in which they live and while in many instances the men thus obtained are as good as could be obtained anywhere in the world, the fact remains that even in our larger medical centers, while the average of ability, is high, that of scientific achievement is not This is partly because the appointments being made, in the great majority of cases, from the local profession, various influences, social, political and institutional, aside from the scientific attainments of the candidates, are bound to enter into the case In the German university, on the contrary, a most important and distinctive feature is the general rule to call some one from another institution or town when a vacancy occurs This not only allows a much more unbiased judgment of the merits of the men under consideration than is possible where the plan common in this country is followed, but also acts as a powerful incentive to original work throughout the entire country

---

[1] Th[illegible] of course does not apply to [illegible] larger [illegible] who do little [illegible] which it gives with the laity

It may be questioned whether the German system could be made to work in this country without a decided change in the ideals of a large part of our medical men Whether, for instance, a man who had built up a lucrative practice in one of the smaller cities would feel tempted to give up his position and go to a somewhat larger place at the other end of the country, with the prospect of repeating the removing process several times within ten or fifteen years, simply because these moves might be steps toward a permanent location in some great metropolis, or whether, even under the stimulus of such a reward, any large body of young men would spend many years in unremunerative original work, or if once in the way of doing such work, whether they would continue it amid the exacting vicissitudes of active practice[2] In other branches of science there are no such difficulties, the zoölogist, for example, not only feels free to use upon original work whatever time and energy his routine work may leave him, but he does so in the conviction that he can in no other way so certainly advance both his spiritual and his material welfare The result is that in zoology, physics, botany and astronomy America turns out a mass of work which compares favorably with that of any country in the world The physician, on the other hand, however strongly inclined toward the purely scientific side of medicine, finds that its pursuit constantly clashes with the practical side If he has a large practice he finds it hard or simply impossible to do more than keep up his reading and attend to his patients, while if it is small he is apt to think, perhaps rightly, that pulling various social and political strings will do more to increase it than anything he can do toward the advance of scientific medicine Laboratory work not only is generally unremunerative and often, for immediate purposes, impractical, but it is entirely possible for an unworldly man who has a passion for it both to neglect his practice and to actually get behind the times as a practicing physician

It may be said that in offering lucrative professorships and other valuable positions as rewards for original work we are not appealing to those highest motives which should animate the scientific mind, if the best work is to be done This is true, the very best work is apt to be done only when a man of the highest intellect, energy and single-mindedness has the leisure and opportunity to seek the truth solely for the truth's sake or for the sake of his fellow-creatures, and of this most fortunate combination I know of no more shining example than the Anglo-Saxon, Charles Darwin But what concerns us now is to find some means for getting a large amount of useful work done by men who are entirely competent to do it, but who will not do it unless some more powerful incentives than love of truth and man can be brought into play In Germany such an incentive is the university system I do not say that the same plan can be made to work equally well here, but simply that if it can not, so much the worse for the future of American medicine

It may seem that the foregoing lines lay too much stress on experimental and laboratory work as factors in medical progress, and to avoid this misconception let me state that I fully appreciate the necessity of all other kinds of serious research The man who for years crowded with experience gives accurate and keenly objective reports of his cataract operations, or the man who gives systematic thought to any of the more abstruse problems of ophthalmology or who works at the careful collection and sifting of the literary and clinical testimony on any particular subject may be doing original work of a much higher and more useful kind than he who spends the same time with his eye glued to the large end of a microscope I also appreciate the fact that the inventor of an ophthalmoscope, or an intestinal button, or a new lid-stitch, may do more for suffering humanity in a few moments than another who delves for a lifetime in the laboratory But such fortunate flashes of intuition come rarely and do not alter the fact that the only sure way for the average man to contribute to medical progress is by the patient and systematic search for new facts

GLIOMA OF THE RETINA

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7 10 1898

BY J L THOMPSON, M D
INDIANAPOLIS

In the eye section of the Ninth International Medical Congress, an eminent specialist of Paris said "I have seen but four cases of glioma of the retina' This struck me as being a very small number, and led me to look over my records of the years 1871 to 1898, inclusive I shall, therefore, briefly report them as follows

Case 1 —Girl, aged 1 year, was brought to my office August 29, 1893, with glioma of the right eye, which was described in Vol iv of Knapp's Archives of Ophthalmology, in 1874, the clinical history by myself, the anatomic by Dr Knapp As the subsequent history was not published, I recently wrote to the child's mother for data concerning other members of the family who have since died of this disease Her letter, which I here produce, will explain the whole matter

"At your request I will try to give you the desired information First child affected with cancer of the eye was a boy, born Sept 9, 1869 Disease noticed when born No medical attendant Died August 27, 1871 Second child, girl, born August 23, 1872 Disease noticed in right eye June, 1873 The eye was removed by yourself, Sept 2, 1873 Cancer came in the other eye about seven months later and she died August 11, 1875 Third child, boy, born October 29, 1880 Cancer discovered in the eye at the age of three months Died January 24, 1882 Fourth child, girl, born Sept 8, 1883 Disease noticed in right eye in February 1885 Died March 5, 1887 Fifth child girl, born Sept 29, 1888 Disease noticed in right eye February, 1890 *Died* July 5, 1891 I am *fifty five* years old, the mother of fourteen children—seven boys and seven girls I have always had good health I have lost no other children—but the five who died of the cancer of the eyes. I did not know my husband's people, but an old lady who did, told me that a greataunt died of cancer of the breast, and that she had three children who died of cancer of the eye. My last three children's eyes did not get so large as the first two, but they suffered with their stomachs. It was impossible to get any food to stay on their stomachs."

---

[2] Perhaps a still more doubtful question is whether young men with a good start in some large city would accept calls to small towns with the readiness of the Germans

(Comments on these cases will be reserved for closing remarks.)

Case 2.—Girl, aged 4 years. Parents negro. Brought to me April 28, 1874, with a gliomatous tumor, which entirely filled the right eye and so pressed upon the iris as to cause much pain. The pupil was widely dilated. The eye was enucleated, simply for the purpose of relieving pain. Death three months afterward.

Case 3.—Boy, aged 5 years. Parents German. No cancerous history is found. Consulted me January 9, 1877. Glioma of right eye. Vitreous chamber entirely filled with the growth. Pupil widely dilated (T+3). Child suffered greatly. Enucleation January 11, 1876. Death from brain trouble, July, 1876.

Case 4.—Boy, aged twenty months, was brought to me Sept. 10, 1878, for the purpose of having what the parents and their physician supposed to be a cataract removed from the right eye. But when I told them that it was a malignant tumor, which should be treated only by removal of the eye ball, they went home. I learned afterward from a physician that the child died of brain disease in the following year.

Case 5.—Girl, aged 4½ years. The parents consulted me May 21, 1880. They had noticed the peculiar metallic reflex from the fundus of the right eye some months before. The growth entirely filled the eye ball and pressed upon the iris. No anterior chamber. Pupil widely dilated, pain great, enucleation May 25, 1880. Child died in the following December.

Case 6.—Boy, aged eight months. Glioma in both eyes. Parents healthy, had noticed the growth in the left eye soon after birth, but had only seen it in the right eye a few weeks before they consulted me, on July 12, 1883. No operation. I learned that the eyes protruded from the orbits soon after they returned home, and that the child died of brain disease about ten months after their visit.

Case 7.—Boy, aged 4 years, brought to my office July 5, 1884, for the purpose of having an operation for cataract. The growth filled about half of the posterior portion of the eye. When told that it was cancer, and that the eye should be removed, the parents objected, returned home, and, as I learned from their physician, the child died in convulsions nine months afterward.

Case 8.—Boy, aged 2½ years. The parents, who consulted me, had noticed a peculiar shiny appearance in the eye several months before they brought him, which was on February 9, 1886, when the tumor filled about three fourths of the vitreous chamber, and seemed to contain two lobes of unequal size. The pupil was a trifle larger than that of the other eye, but quite movable (Tn). Enucleation the following day. I saw the child two years afterward, and there was no sign of the disease in any other organ, and he is now in perfect health, twelve years after the first consultation.

Case 9.—A fine looking boy, aged 2 years, of very intelligent German parents, who brought him to me on October 11, 1888. They had noticed the bright reflection from the eye some months previous to their visit. The pupil was but a trifle larger than that of the other eye. After dilating it, a well marked lobated glioma was found. When the parents were told that it was a cancer, they were terribly agitated, and they immediately commenced consulting all the prominent eye specialists of neighboring cities. I removed the eye ball on Nov. 23, 1888. He had an artificial eye put in about ten months afterward, and I occasionally see him upon the streets in perfect health, ten years after the enucleation.

Case 10.—Boy, aged 2 years, was brought for examination on October 11, 1890, with gliomatous tumor, which filled about two thirds of the vitreous chamber of the right eye. The pupil was normal in every way. I advised the immediate removal of the globe, but the parents objected, went home, and did not return until eleven months afterward, when the tumor had pierced the back part of the sclerotic coat forcing the globe partly out of the orbit. My son enucleated the eye ball simply to relieve pain. The child died six weeks afterward with brain symptoms.

Case 11.—A beautiful girl, aged six months, with fine looking, healthy parents, who consulted me on December 26, 1896. The gliomatous growth filled a little more than half of the back part of the vitreous chamber of the right eye. The pupil was slightly dilated, but movable. It was a typical case of gliomatous tumor, with its well marked lobes, as usually seen in such cases. When the parents were told that it was cancer, and I asked about the family history, I learned that the father's grandmother died of cancer of the uterus. The eye ball was taken out on December 26, 1896. The child returned home on the fourth day, and is now perfectly well, eighteen months after the operation.

Case 12.—Boy, aged 2 years, was brought to me for consultation November 10, 1897, with well marked gliomatous tumor, which filled three fourths of the vitreous chamber of the right eye. Dr. Thomas of Logansport, an eye specialist, who sent the case for my opinion, enucleated the globe the next day. He wrote me a few days ago that the boy is now in the best of health, with no sign of a reappearance of the disease in any of the tissues. But as only six months have elapsed since the globe was removed, it is too soon to state the result.

Case 13.—Girl, aged 3 years. Her mother, who is a delicate looking woman, brought the child from an adjoining state, just as I was finishing this report, May 20, 1898, with a gliomatous tumor of the left eye. The parents first noticed it about one year before, but as their physician told them that it was a cataract, they put it off until it caused great pain, and made the eye to protrude. When first seen there was much inflammation of the conjunctiva, and three fourths of the globe was prolapsed. The eye ball was removed simply for the relief of pain. Of course the child will die.

REMARKS

The first point which calls for inquiry is the large per cent of cases met with in my practice. The gentleman referred to as having seen only four persons suffering from glioma of the retina is known to have then examined fifty thousand patients. My private records show a trifle over twenty-four thousand five hundred patients examined, and thirteen cases of this disease. (It is possible that I have overlooked one or more.) Add to the thirteen four cases reported by the mother of my first case, and we have seventeen cases of glioma.

Can climate, or soil, or temperament have anything to do with its causation? Two of my patients were of German parents, one negro. All the others were native born, as were their parents. All but one family had lived long in Indiana. The one out of the State resided in the adjoining State of Illinois, both of which contain very flat lands. In the seventeen cases, ten were found in boys, seven in girls. The right eye was affected in thirteen, the left in two, both in one case, and in one the eye affected was not mentioned.

In seven of these children the eye was not removed, and they all died within a year after they were examined. Ten eyes were removed, but in three of them it was too late to expect anything from the operation, except the relief of pain. Three of them are cured. Of the two others now living, one which had the eye removed six months ago has no symptom of the disease left, but it is too early to speak of a cure. The last one, which had the eye-ball removed but eleven days ago, will doubtless die.

It will be seen that three of these patients were supposed to be troubled with cataract by their attending physicians.

One question arises. Were the cases which recovered true gliomatous tumors? The answer is: They were, most undoubtedly. Indeed, I can not conceive of the possibility of a mistake being made by any practiced and careful observer. How could one fail to differentiate between a gliomatous tumor, with its anfractuosities and well-rounded convolutions, and any condition of the fundus of the eye which has resulted from inflammatory conditions?

Pseudo glioma is a misnomer, and should have no place in ophthalmic literature. Not only were these cases examined macroscopically, but they were sent to some of our most expert microscopists and pathologists Dr Weeks of New York and Dr Wynn of Indianapolis pronounced them to be true cases of glioma

In presenting these cases for your consideration, my chief aim is to emphasize the fact that glioma of the retina is not necessarily fatal, but that many cases have been, and can be, cured by early enucleation

DISCUSSION

Dr C M HOLMES, Cincinnati—I have seen four cases of glioma, and unfortunately the first three were not operated upon in time, that is, they refused operation, although I believe the cases were seen early enough I have one case that was operated upon about one year ago, and in which there has not been the slightest return so far, but statistics prove that even that is not sufficient time to warrant pronouncing a cure The question as to whether there is such a thing as glioma, or whether these tumors should be classified with the sarcomata, is now under discussion by the microscopists In the last case I had very careful microscopic sections were made, and it seemed to demonstrate the opinion of some expert pathologists that the glioma, as we call it, nearly always arises from the inner, granular layer of the retina Hence there is now a desire to reclassify this tumor and put it with the sarcomata It is not yet a settled fact, for recent German pathologists still classify it by the old name

There is one thing certain we must see our cases early, and we should insist upon operating or have nothing more to do with the case, and if we do this I believe we will get the consent to operate more frequently than we have done I think one reason for the frequent refusal has been that we have not been firm enough

Dr FRANK ALLPORT, Chicago—I have seen two cases of glioma of the retina, and both were examined microscopically by Dr Holden of New York Both of these cases occurred in children, one a child about 3 years old, who was operated six years ago by enucleation That child is well today and has had no signs of a recurrence The glioma did not extend beyond the globe The other case came to me three years ago, and when first seen the glioma had extended beyond the globe The eyeball and tumor were removed and the child died of a recurrence of the disease one year ago So one of my cases died and the other has not, though six years have elapsed without any apparent evidences of recurrence

Dr J E MINNEY, Topeka—I have seen four cases, of which two are living One was seen in consultation with Dr Longnecker some six years ago and was proved by pathologic examination to be that form of cancer That little girl is living today

The most interesting case I had was that of a little girl 12 years of age, in whom we diagnosed glioma of both eyes One of the eyes was giving considerable pain and we removed it We exhibited it to a pathologist and it proved to be the characteristic glioma, or sarcoma, as some call it now The second eye was affected in the same way and total blindness occurred in six months That eye was removed four years ago and the girl is in a blind asylum today

Dr E C ELLETT, Memphis—I should like to report two cases The first occurred in the practice of a friend of mine who enucleated both eyes of a child 1 year old All the orbital contents were removed and one eye was sent to Dr Prudden of New York, and the other to a pathologist in Brooklyn They agreed in the diagnosis The patient is now, after eighteen years, a healthy individual

The other case was a child 2 years of age, brought to me in April, 1897, with the history that since birth the right eye had been noticed to greatly enlarge and, as the mother expressed it, "something white could be seen in the pupil" The eye had begun to shrink some weeks before I saw it I thought it was a case of detachment of the retina, and as the examination did not cause me to suspect anything more than detachment, I advised taking the child home In August of the same year the process began in the other eye and they brought the child to Memphis to consult another oculist, who made the diagnosis of glioma and enucleated that eye The child died this year of a recurrence

The eye which was affected when I saw her did not up to the time of death present any evidence of further advancement of the process whatever it was, and of course it must remain a question whether it was detachment or glioma in the first eye

Dr GARTEN—Dr Thompson quoted an authority who had examined 50,000 cases and had seen but three cases of glioma My impression is that there is not a man here who can not report one or more cases that have come under his notice, and the question arises, are we all wrong in our diagnoses? I have seen four cases myself and would report about the same results as given by the other gentlemen

Dr T A GRIGG, Butte, Mont —I would like to say a few words upon this subject and would like the gentlemen who discuss it further to give an opinion along these lines, that is whether in operating for glioma they simply enucleate the eye, or whether they remove all the orbital contents at the same time, would not the results be better by removal of all the orbital contents?

I have had two cases operated upon in this way, one of three years' standing now, and there has been no recurrence Dr Thompson did not state how his operations were done, whether enucleation simply was done and the orbital tissues left for cosmetic effect or whether the contents had been removed

Dr H V WÜRDEMANN, Milwaukee—I am pleased to learn from Dr Thompson's large experience that there has been such a large proportion of recoveries after operation I have seen out of about 8000 cases, 5 of glioma of the retina and 3 of these have come to operation All of these cases have died within six months after the first diagnosis The trouble with most cases of intraocular tumor, as you all know, is that many of them come to us too late to insure a satisfactory prognosis They come when inflammation has set in and the eye has become infiltrated with new cells The question of diagnosis of glioma is one that it seems to me is readily determined by the history There are a number of inflammatory affections of the eye that on ophthalmoscopic examination, may seem to look like glioma, but the diagnosis can be made from the history, together with the existing conditions As a rule there is no tension, there is inflammation, and the ophthalmoscopic appearances are almost characteristic The cases are all fatal if not operated upon

I have a specimen of glioma here, which I pass around for examination It was diagnosed within a few months of its inception but an operation was refused Three months later the patient came with an eyeball full of the tumor mass, and I enucleated with slight hope of saving the patient's life The tumor reformed in the orbit and the child died within three weeks This section shows very well why, when we operate at so late a date, we meet with failure

Dr CHARLES H BEARD, Chicago—I have had several cases of glioma occurring in dispensary practice upon which no report has been made, and in only one of which did we get a microscopic examination That case was a little baby less than two years old The patient recovered and reports to me now from time to time Another case which occurred in my private practice is that of a little girl who also reports to me occasionally Those are the only two cases that I have treated which I know to have been glioma and which I know to have recovered

Dr C D WESCOTT, Chicago—I wish to mention one case of interest from the standpoint of the diagnosis The patient was a child 3½ years of age, first seen when the symptoms had existed for one year The clinical diagnosis of glioma was made The tension was up and the eye slightly painful at times Microscopic examination demonstrated the fact that the tumor was a non-pigmented sarcoma of the choroid Tumor cells were found in the optic nerve and in three months the tumor was visible in the orbit I exenterated the orbit after six months, but the child died six months later of another recurrence

Dr J O McReynolds, Dallas, Texas—I have been very much interested in this subject, especially with reference to pseudo glioma, because I have recently had a case which seemed to belong to that type I have seen only four or five cases of glioma, about half of which have been fatal The case of pseudo glioma occurred in my practice about two years ago and was observed by others I advised removal of the eye, the growth having been in progress about three years I saw the patient about a week ago, and he is in perfect health without recurrence An examination of the eye afterward showed it to be a pseudo glioma, that is, it was not regarded as true glioma I would like to know whether there is such a thing as a pseudo glioma This case was first diagnosed as detachment of the retina and progressed for several years without increase of tension

Dr H M Starkey, Chicago—I will pass around to go with Dr Würdemann's specimen, two cells containing the hemispheres of an eye enucleated by myself one year ago last March Macroscopic and microscopic examination shows it to be glioma As there has been no return of the growth, we may reasonably hope that there will be none

The eye was removed the day following that upon which the child was first seen The tumor had not penetrated the globe, nor had it extended along the optic nerve, which was severed well back in the orbit

The statements of the comparative rarity of glioma have been a little surprising to me, as the proportion of cases of this disease coming under my observation is much greater than that given by most of the German writers

In two of my cases the removal of the eyeball has seemed to have entirely eradicated the growth, the case mentioned above and another seen in perfect health sixteen months after the operation

Dr D S Reynolds, Louisville—I do not wish to prolong the discussion, but I am amazed at the opinions expressed and am tempted to cull just a little from memory, for I have no record with me now to quote from It seems to me that in thirty years I have seen more than a dozen cases of glioma In 1869 I saw my first case in a child about two years of age She still had sight in the eye, but it was noticed that there was a little yellow reflex on looking into the shaded pupil Examination showed a tumor by the side of the optic nerve entrance I pronounced it in all probability a glioma and suggested enucleation The late Dr Sloan, of New Albany, advised that we wait a few weeks and see the child again That was done and the tumor had almost doubled in size I operated and the other eye did not show any manifestation of trouble until 1873, when she began to have a little irritation in that eye An examination showed the same kind of golden colored tumor, clearly within the retinal substance The eye was enucleated and microscopic examination showed it to be a glioma purely within the retina and not invading the other structures except the contiguous portion of the choroid

As to there being such a thing as a pseudo glioma, I take it for granted that diagnosis was not clear, it means something else, and not glioma

I am sure Dr Wescott's case can be duplicated by many other gentlemen I have known them to invade not only the globe, but all the orbital tissues, as I have more than once reported cases of this kind I have stood as almost the single advocate, in my part of the country, of enucleating all cancerous eyes, and scraping out the tissues of the orbit for cancerous growths

I had an old blacksmith upon whom I operated in 1875, and who recovered his health, went back to work and enjoyed comparative comfort for five years, when the tumor again appeared and he finally died of cancer in other organs At the time of operating a mass of cancerous tissue as large as the patient's head protruded from the orbit.

The exact counterpart of these tumors is found in the optic nerve and in the brain It is essentially a tumor of nerve structures, and if not, it is not a glioma I have operated in cases of glioma and had the misfortune to see the tumor appear elsewhere and the patient die I know of no complete recovery except the first mentioned case and she, for many years, was a teacher in the institute for the blind

Dr Flavel B Tiffany, Kansas City—In my experience of twenty years I can recall eight cases that I have had, three of them double In these cases all were under seven years of age, and I believe that it is the experience of all of us that glioma appears in the young only My cases, with the exception of two, were negroes, and it has occurred to me that this disease may be more frequent in that race than in the white, and that perhaps that would account for our seeing more cases in this country than are seen in Europe

When the eye is ruptured and the tumor protruding I exenterate all the orbital contents, but if the tumor is confined to the eye I can only enucleate

Dr Boyd—I can only report one case but that is a rather peculiar one, for I found that two others in the same family, brother and sister, had died of the same cause The father and mother were both healthy My case died, making three out of five children to die of glioma of the retina

Dr R F LeMond, Denver—I have seen three cases of glioma of the retina and can not agree with Dr Tiffany that they occur only in the young, for of my cases one was 52, one 55, and the third, now under treatment, 53 I operated upon two of them and one died

Dr Herbert Harlan, Baltimore—One of the gentlemen laid some stress upon the importance of urging upon the patient the necessity of having the operation performed I have lately seen a case that has caused me to give much consideration to that point The patient is a child 8 months of age, and in March last the mother noticed something white in both pupils The pupils were partly dilated and the child could see objects and take hold of them The diagnosis of glioma in both eyes was made and I have seen the child every three weeks until a few days ago There is no evidence now of perception of light, though the pupils react slightly to strong illumination This happens to be the child of an intelligent physician, who understands the matter thoroughly, for he has had the opinions of three oculists, and he declines to permit interference in any way So while it is well to advise operation there are some cases in which it is impossible to do what we think best

Dr D C Bryant, Omaha—I would like to add about a half a dozen cases to those reported Three of them were seen after perforation had taken place, but before any extensive growth had occurred outside In these cases all the contents of the orbital cavity were removed, but a short time afterward recurrence took place and death followed In the other three cases, where there was no perforation, two had a return a short time after enucleation and died The remaining case was enucleated four years ago, has had no symptoms of return and the patient is well This was a child about 1½ years old

R. L. Randolph, Baltimore Md said that Greef had recently made some observations in regard to the histology of these tumors which he has been able to confirm Randolph has noticed that in sections of gliomata stained with hæmatoxylin the cells immediately about the blood vessels are more deeply stained than those lying at points remote This gives to the tumor almost the appearance of angioma This condition is to be accounted for in a large measure by the high intraocular tension, which has the effect of squeezing out the life of the cells remote from the blood vessels, and consequently these cells appear in the sections necrotic, while those surrounding the vessel retain their vitality and stain deeply Recent work has shown that the tumor does not originate, as was once thought, from the external or from the internal granular layers It will be remembered that the cells in a glioma morphologically resemble those in the granular layers of the retina, and this seemed a strong reason for supposing that here the tumor originated Improved methods of staining, however, have shown that the tumor cells are not only like those in the granular layers, but that they are of different sizes and shapes, some being oval and some having processes and resembling a rosette The theory as to the origin of these tumors is new It is not an uncommon thing to find in a normal retina cells which are out of place, that is to say, cells in one layer which morphologically belong to another layer, as, for instance, ganglion cells in the internal granular layer, and vice versa These cells have been called by Cajal, Wintersteiner, Greef and others, misplaced cells and these observers have noted that gliomata are made up largely of these misplaced cells The conclusion is then that a glioma orignates from a cell which is misplaced in fetal life, and which misplacement may occur in any one of the retinal layers

Dr Thompson—In closing I would like to say that those cases which have returned have done so inside of seven months I have never had a patient over 6 years of age with glioma I can recall tumor after tumor of a sarcomatous type, but they have been after 7 years of age, so I conclude that age assists in the diagnosis One gentleman asked whether I took out all the tissues of the orbit in my operations? No, I do not think of any such thing if the tumor is confined to the eyeball I enucleate, cutting the nerve as far back as possible, if the growth has burst through the globe then I remove all the orbital contents If I could have taken the time to have read all of my paper you would have seen why I operated differently in different cases

I can not conceive of a person confusing glioma with detachment of the retina if the patient is seen in private practice Such a mistake might be made in the hospital, where in seeing a large number of cases you make a snap shot

As regards pseudo glioma, as one gentleman has said, it is either glioma or it is not glioma It is glioma I was talking about If any gentleman here should mistake these two conditions I should be inclined to pay no attention to him at all

I think we should advise early enucleation, and tell them they will die just as sure as can be if they do not have the operation performed Then I presume those that die are glioma, and those that do not are pseudo glioma

---

A CASE OF "MATHEMATICALLY-PERFECT EYES"

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo , June 7-10, 1898

BY GEORGE M GOULD

PHILADELPHIA PA

On Oct 12, 1897, I was consulted by a gentleman 50 years of age, whose chief complaint was of subconjunctival hemorrhages, which had occurred on an average every two weeks during the past year I found that he had consulted a great many oculists during this time who had either given general treatment for gout (of which there was some slight evidence) or had sent him to the general practitioner, or had only prescribed reading-glasses, etc The hemorrhages seemed to come on spontaneously and were bothersome chiefly because they gave the man such a frightful appearance, and caused mental worry, rather than any decided pain or trouble of vision One eye was generally affected at a time, and as the hemorrhage only stopped when the subconjunctival space was thoroughly filled with blood, the appearance of the eye and patient is easily imagined I frankly asked the gentleman what he supposed I could do for him when the large number of the best men of the city had failed His own faith was plainly little, but I was compelled to try General disease of any pronounced type was excluded by thorough examination, the family history and personal history were beyond reproach, and one of our most careful "internists" had treated him on general principles for this one ocular symptom without influencing it in the least The muscular co ordinations of the eyes were as perfect as they could be, and by all nonmydriatic tests both eyes were absolutely emmetropic, the visual acuity was 20/20 + Indeed the man had soon told me that he was an optical curiosity, other oculists having marvelled at the emmetropism of his eyes, and one especially—a man of large practice and scientific ability, had repeatedly said that his was the only pair of "mathematically perfect eyes" he had ever seen It was certainly a gloomy outlook for the man with a fad —the "oculist hobby rider "

Relying however upon the results of many experiences, I proceeded to work upon the basis of what have become axioms with me, viz *No mydriasis, no diagnosis of refraction* and, *all presbyopia is only relative* Under a mydriatic I found the visual acuity as perfect as it had been without it Then I comforted myself with another maxim *Perfect visual acuity is no proof of the non-existence of an error of refraction*, and I was soon able to demonstrate an error as follows

R —Cyl 0 25 D ax 90°
L —Cly 0 25 D ax 180°

Now I did not say to myself that this tiny error of refraction was the cause of the conjunctival hemorrhage, I did not then dream that it was, and told the patient that if any local cause for this existed I believed it to be due to the failure to use presbyopic glasses while eating meals, card-playing, etc With this end in view I ordered bifocal spectacles, for distance the cylinders as above, and for near a proper spherical added Then came downright rebellion, the man was mad at the idea of wearing the "hideous things " I said, then, that this was my prescription, and, unless followed, I stood discharged He went away savage and disgusted, but did order the bifocals, wore them part of one day, and more wrathful than ever, ordered the optician to turn them into separate pairs of eye glasses As I had washed my hands of the case, I allowed the optician to do as the man desired, and not seeing him again I supposed he had left me for another and a less dogmatic adviser I had quite forgotten about the matter, when in two months my office-boy brought up a bill my secretary had sent the man, with a check to pay it, saying the gentleman had asked to have the receipt signed, would not come up, etc Luckily I remembered the name, and returned the receipt by my own hand, impelled by a certain quizzical curiosity He was evidently in a very different mood, said he did not want to trouble me, intended writing, etc , but was glad now to tell me how happy he was with his eye-glasses I have seen him several times since and to shorten an overlong story I will say that not only has there been no recurrence of the hemorrhages, except one very small one, since getting the glasses, but a previous discomfort uncomplained of, and hardly recognized, is completely relieved, but returns at once if the low cylinders are not worn, this discomfort is now so decided that he has had made heavy steel spectacles to wear in his bath, the sense of pressure and irritation becoming so great even in a time so short as that

I shall not now attempt to explain the *modus operandi* of a low astigmatism producing so severe and unwonted a result as these hemorrhages That it did produce them I have not the shadow of a doubt, and the method is perhaps readily enough divined by all of you There is only a single negative I wish to emphasize, and this is the reason I have gone into the rather gossipy details of this case, there is not the least crevice through which may creep the suspicion of hypnotism or autosuggestion The man was mad at me, and I was provoked at him, he refused to follow orders, had no faith in the diagnosis or the doctor, and as a last climax-clap, I was utterly mistaken in my diagnosis! It was not the need of bifocals, or of presbyopic correction, that was the true etiologic factor but simply the low myopic reversed astigmatism The fact of this only came out through unfaith and indirection by wearing the forbidden eye-glasses

This has led me to entitle this report a case i e, an instance of disease of emmetropically-perfect eyes and so many lessons are suggested by it, lessons which I myself have long needed, and which, perhaps, one or two of you may profit by, that I have been moved to report the case, chiefly for the fun of tne *hæc fabula docets* These shall be most briefly recaptulated

1 The most important lesson that springs into view one which every day, and in every journal, and in every other case-report, should be printed in double caps is this Although a patient has been examined by one or more good oculists, and glasses prescribed or reported as not needed, the fact has no significance whatever It does not prove that eye-strain does not exist, nor that it is not a source of any of the results that eye-strain may produce This seems extreme and even revolutionistic, but it is literally true In this case the proof of the pudding is not in the eating There are a hundred qualifications needed to the bald statement that "glasses did not lessen the symptoms," or "the oculist reported the eye-examination was negative," or "eye strain was ruled out by careful tests,' etc I do not care a button for sudh assertions they are simply meaningless unless very many other considerations go with them Do not for an instant think I make an exception of myself, or wish to cast any slur upon the work of others that would be simply silly What I mean is, that in these infinitely delicate matters, in these calculations of infinitesimals, slight differences, inobviable personal equations, etc may indeed occur and be the reason of failure, but beyond all this there are numberless questions e g, as to correctness of make and accuracy of adjustment of the glasses as to methods of wear or non-use as to habits and peculiarities of eye-work, as to length of disease, as to suddenness of consequent refraction-changes as to the frequent impossibility of curing a result by curing its cause as to complicating causes as to intercurrent general diseases, etc Not only in the case reported but in hundreds more I have learned that my own errors, mistakes and blunders, as well as those of others, may show the fallacy of a single judgment, a multitude of provisos must be excluded and the subsequent history closely scanned in order to prove or to disprove the lumpish dictum, "glasses gave no relief ' Facts are stupid and useless things without an intellect to discriminate, marshal and use them It takes more than a lot of rocks to make a lock or a breakwater

2 A very slight uncorrected error of refraction may be the cause of strange and serious reflexes and results, and this is especially true if it be unsymmetrical astigmatism, and still more surely if it is a low degree myopic astigmatism, in which there are no means of escape by blunting into amblyopia, or by shunting into heterophoria, and no possibility of ciliary-muscle contraction overcoming the defect

3 Low-grade myopic astigmatisms are hard to diagnose, and are in practice too commonly overlooked and neglected, although they must be as common relatively as hyperopic varieties

4 It is only by the mydriatic, combined with infinite patience, delicacy, and skill, that such astigmatisms are correctly diagnosed Perfect visual acuity is no disproof of coexisting ametropia

5 The mydriatic is more necessary in presbyopia than previously All the text-books and teaching is wrong in this Precisely when the compensatory mechanism is being narrowed by presbyopia, is then the greatest need of accuracy in the correction of the smallest degrees of anisometropia and astigmatism Then, also, the vital powers are failing and the cataract age is nearing, so that precision in refraction is doubly and trebly imperative Presbyopia is always relative, never absolute, particularly if proper glasses have not been worn during many previous years Without a mydriatic there is no accurate estimate of errors of refraction, and between the ages of 40 and 55 the estimate should be painstaking to the uttermost degree, especially if any suspicious reflexes exist

6 Absolute emmetropia, "a mathematically perfect pair of eyes," does not, I believe, exist A perfect leaf has not been found, nor absolute symmetry in any organic thing The report of perfect emmetropia is a confession of negligence and unskilfulness I have made such reports myself and can therefore speak dogmatically If such a diagnosis has been made without a mydriatic the negligence deserves a much harsher naming

7 And even if there were such a mathematically perfect pair of eyes, I can easily imagine circumstances in which the use of such eyes might be the cause of morbid results As othophoria is always a disease, so emmetropia, in a seamstress or in almost any hard-pushed eye-worker, in a neurasthenic, in a heterophoric, or in a presbyope, may functionally be a disease and require correction by glasses Emmetropia is nature s unrealized ideal for the animal, savage and primitive man A low degree simple myopia, alike in both eyes, is the desideratum of the slave of civilization

To focus this long winded reading into a sentence I should say that when a possible or suspicious ocular reflex exists, painstaking mydriatic refraction and correction are necessary both in presbyopia and in "a mathematically perfect pair of eyes And when this has been admitted comes the rider that even after all has been done it can not, with utter certainty, be said that the eye strain was not, or is not, the ultimate source of the morbid symptom

Since writing the above my friend, Dr H O Reik of Baltimore, sends me the following note

> On Feb 1, 1898, a lady, aged 30 years, consulted me because of slight subconjunctival hemorrhages of both eyes, which, she said, had recurred a number of times without any known cause She was otherwise in perfect health She remembered that during her high school life she had been subject to somewhat similar attacks, which came whenever she was doing an excessive amount of reading and study Lately she had been using the microscope very constantly and had also been reading a good deal These were none of the usual asthenopic symptoms Vision was perfect, and there was no manifest hypermetropia The muscle balance was also good Examination under homatropin showed the following error
>
> R E —C 0 50 D ax 90°
> L E —C 0 50 D ax 180°
>
> The above glasses were prescribed, and since that time she had no more trouble of the kind
>
> I find in my record book the diagnosis "subconjunctival ecchymosis due to refraction error "

It is noteworthy that the error causing the trouble in both the case of Dr Reik and my own, was a low degree of myopic astigmatism at reversed axes

DISCUSSION

Dr C B **Wescott**, Chicago—I am sorry we could not have heard the last page of this paper I have always been a firm believer in the use of mydriatics after the age that they are usually thought of by my brothers and fathers in the profession Since my visit to Philadelphia, last year, I have been using them in my older patients I think the oldest was 64, and I must say the more I use them the more satisfactory I find them I quite agree with Dr Gould, that it is fully as important to correct the low degrees of errors of refraction after forty years as before, and I am doing it with great delight

Dr J E **Minney**, Topeka—I want to emphasize one point the doctor made I was two years getting proper glasses when my error was very small Secondly, I believe the blood vessels of that man's eyes were not normal, and I would suspect that there would probably be in the future some brain lesion, and if it was a case of mine I should warn the patient to be on guard

Dr G C **Savage**, Nashville—The question of why astigmatism should be more troublesome if vertical in one eye and horizontal in the other, has not been fully set forth, so far as I know I believe the increased trouble experienced by patients of this kind is due to the fact that the visual axes, in order to harmonize images, throw upon the recti muscles the necessity for breaking their regular movements We all know, as set forth in a paper by Dr Jackson, that the image is elongated in the direction of the meridian of greatest curvature If elongated horizontally in one eye and vertically in the other, the superior rectus of one eye rises to one point and that of the other must go a little beyond it, and, so in going from side to side, for there must of necessity be fusion of images of the part looked at If one axis has to go so far and the other farther, you can see there is at once a disturbance of harmony I believe that astigmatism against the rule in one eye and according to the rule in the other, is of more importance to patients on this account

Dr **Harold Gifford**, Omaha—While I started out as a skeptic concerning the correction of so small a degree as one quarter dioptre, I want to report that I have obtained a good result in one case, that of a homeopathic physician, by prescribing a one eighth dioptra glass

THE GALVANIC CURRENT FOR THE TREATMENT OF PTERYGIUM

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY HORACE M STARKEY, M D

CHICAGO ILL

Since electricity has been used in almost every diseased condition of the eye and its appendages, from senile cataract to stricture of the nasal duct, a brief enumeration only of these various uses would consume all the time allowed This will not be attempted, but attention will be confined to the use of electricity in one condition—pterygium

Six years ago at the Detroit meeting of this Section, the writer made a brief statement concerning the treatment of pterygium with a weak galvanic current, which he had been employing with apparently good results for about two years, and requested members of the Section to give the method a trial While he is not aware that that request has met with any response, he has continued to employ the method then outlined, and longer experience has convinced him that it has decided value in suitable cases

In September, 1889, the writer, who was at the time much interested in the study of electricity, saw a pterygium that it appeared to him at once would be favorably influenced, if not entirely removed, by the galvanic current The pterygium was small, the apex just commencing to encroach upon the cornea, and was composed of a few large blood-vessels with a minimum amount of connective tissue and thickening of the conjunctiva The patient was seen but for a few moments and promised to return in a few days for further examination and treatment He did not, however return for nearly a year, and in the meantime no other case was seen in which the conditions seemed favorable for the treatment

June 2, 1890, however, the patient, S J F, age 36 machinist, referred by Dr Creighton, returned, and the proposed treatment having been explained to him, he consented to a trial of it, and the positive pole, a platinum needle, carrying a current of three milliamperes was used in the method to be described The current was passed through the pterygium in three lines for one minute at each place, with the inevitable result that the lumen of the enlarged vessels was closed The patient was to have returned in a few days for observation and further treatment, but nothing was seen of him for nearly a year, when he was met upon the street In answer to inquiry as to why he had not come back, he said that the eye had been entirely cured by the one treatment, and that he had not thought it necessary to return An inspection showed that the enlarged vessels had disappeared and that there was but a very slight thickening of the sub mucous tissue remaining The patient has been seen from time to time as late as 1896 when, notwithstanding several attacks of mild conjunctivitis, the pterygium remained unchanged For two years now he has passed from observation This case is given somewhat in detail, and while it is the first case treated in this way, it is the most brilliant in its results

Since this first case from two to four pterygia have been treated in this manner each year in private practice, nineteen in all, and about the same number in dispensary and hospital work In every instance the pterygium has been reduced in size, and in most cases the growth has been entirely checked, and while in about 50 per cent of the cases the cure has been radical, in about 20 per cent the growth has recommenced at a later period, and some form of operation has been necessary The percentage of recurrences has been less than after excision or other operations commonly employed, and the recurrences have been nearly all in cases that were unsuitable for electrolysis and where some other form of operation should have been adopted

The cases which seem to be suitable for electrolysis are those with small pterygia, not encroaching much upon the cornea, and particularly those in which there is considerable enlargement of blood-vessels Experience seems to show what a knowledge of the action of electricity upon the tissues would lead us to expect that commencing pterygia that are as yet too small to be harmful may be entirely checked by two or three treatments so that they remain quiescent indefinitely A number of cases have also been treated in old and feeble people who evidently had but a short time to live and in whom the dread of operation was very great In these cases the sight has been improved, irritation allayed and both the patients and their friends have been very grateful for the relief obtained The way in which the electricity acts upon the tissues is as follows

1 It coagulates the blood in the vessels, thus stopping the blood current and causing the vessels to disappear 2 It produces a mild adhesive inflammation of the sub-conjunctival tissues, thus forming a firm cicatrix between the conjunctiva and the sclera so that the gliding of the former over the latter is prevented, and 3, it destroys micro organisms in the tissues, so that, if the claims advanced by certain investigators that micro organisms are the cause of this disease should prove to be well founded, this treatment would still be rational

These effects are all produced by the positive pole when used as the active agent When the negative pole is used we get solution and absorption of the submucous hyperplasia and of the thickened conjunctiva

The method of employing the current is as follows Any source of electricity may be employed, provided it produces a smooth, constant and certain current of sufficient electro motive force to overcome the resistance of the body, and provided further that it can be so controlled as to deliver a current of from one to five milliamperes The current should be completely under control and should be accurately measured by a reliable milliamperemeter, which should measure fractions below five milliamperes The current at the terminals should be tested before each operation The apparatus being in good order the eye to be operated upon should be cocainized and a fine platinum needle, connected with the positive pole of the battery, should be introduced through the conjunctiva near the apex of the growth, and passed close to the sclera through and beneath the pterygium, and at a right angle to the direction of the growth The circuit may now be completed by having the patient press a well wetted sponge connected with the negative pole against the palm The currents should be turned on till the meter shows that one, two or three milliamperes are passing

This current should be maintained for one or two minutes A second puncture should be made in a line parallel with the first and two millimeters distant, and if it is thought desirable a third may be made The immediate effect seen is the formation of gas, which appears in bubbles upon the surface at the points of entrance and exit of the needle, and which cause some puffiness of the conjunctiva along the line of puncture Considerable hyperemia of the conjunctiva is occasioned, but large vessels with which the needle comes in contact are more or less collapsed The pain occasioned is insignificant, and while there is some feeling of irritation and fullness in the eye for a few days, this has not been sufficient in any case to prevent the patient going about his regular duties The treatment may be repeated in four or five days, or it may be delayed as many weeks, at the convenience of physician and patient

The advantages of this method are First, it avoids any loss of tissue, second, it is painless, third, it does not incapacitate the patient, fourth, it stops the progess of pterygia seen in the early stages With these advantages is coupled the fact that it seems quite as free from recurrences as any other method It is not advised except as a palliative in broad, fleshy pterygia or in those encroaching much upon the cornea

NOTE —It is well to use a small current at the first application that the irritability of the eye may be noted

---

THE VALUE OF FARADISM IN CHOROIDITIS

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY ROBERT F LeMOND, A M , M D
PROFESSOR OF DISEASES OF THE EYE AND EAR GROSS MEDICAL COLLEGE DENVER COLO

The title of my paper is one that would naturally be called somewhat rare among ophthalmologists I have in the last few years come in contact with a great many cases of the various kinds of choroiditis, and have studied the pathology of all the cases very closely The various kinds of choroiditis are more or less akin, that is, in regard to the puzzling problems that they so often present to the oculist from the fact that choroiditis has been so hard to completely cure We have choroidal affections, some of the most common of which it might be well to mention namely the areolar, atrophic, disseminated, simple, plastic and suppurative Now it does not matter a great deal about the different names of these troubles, for they differ more than the real conditions of the choroidal layer, from an etiologic standpoint I have often been very much puzzled to know what has caused this condition of the eye, we so rarely get a history of the case that helps us out, and so frequently we can get no syphilitic history at all, when often that is the real source of the trouble But I believe that choroiditis results from various conditions For instance we have it in extreme cases of myopia, in the various brain tumors that we come in contact [illegible] know are conducive to this character

---

NOTE —Doubtless it is well understood by all that it is not the direct action of the electric current that produces these effects The current decomposes the salts in solution in the tissues into their acid and alkaline constituents, the acids appearing at the positive pole and the alkalies at the negative pole The acids at the positive pole have a charring, contracting and hardening effect upon the tissues of the body and coagulate albuminous fluids, while the effect of the alkalies at the negative pole is to soften, dissolve and liquify those tissues in other cases where the system is depleted and run down So far as my experience goes, I find the majority of cases over 40 years of age, but have treated a number under 30, and my record book shows that about two to one of these cases are in favor of the male sex, as they are more often contaminated with syphilis than the female, and I believe that the majority of these cases originate from syphilis The opacities in the vitreous excite various influences on the vision and in different ways For instance, opacities veil the entire visual field, while a large floating opacity interrupts the luminous rays by moving between the retina and the object, thus destroying perception of smaller objects altogether and very much impairing the visual acuity In the last condition the patient will frequently learn to hold his eye still for a moment, looking directly in front, when the vision improves, the laws of gravity intervening So far as treatment is concerned, we know it has been for a long while a well blazed road, and that we should be very careful and guarded in the prognosis that we give, for fear we make it too flattering and lead the patient to believe that there is nothing the matter The object that would naturally present itself would be to have these floating bodies in the vitreous destroyed, and reasoning upon this from a scientific standpoint, we come to the conclusion that the only way to do this is to absorb them, as we have found from long experience that leeching, scarification and paracentesis of the anterior chamber do not help us out of our dilemma Then we must give something that will absorb this coloring matter from the vitreous, if it can be done The next question is, what are our best medicines for this purpose? We at once decide that the kali iodidi is one and the bichloridi hydrargyri corrosive is another, and the stimulation of the circulatory system, especially the heart, if not at its full normal strength I think the influence of the infusion of digitalis about three times a day is about as good as we can use for this purpose, aside from this it is thought well to stimulate the nervous system also, and a favorite nerve tonic is sulphate of strychnia But we learn from experience in many cases in which these medicines have been used that they will fail to do the work Then we naturally look and inquire in some other direction for a remedy that will do the work, we ask ourselves the question What is electricity? Is it not a stimulant? Stimulate the circulation and nerve centers, and all the functions of the body are excited, and if it is given to anything like full toleration it is certainly one of the greatest stimulants that we know anything of Now I have investigated and looked over a great many authors, and been able to find but little encouragement for using faradism in this character of eye trouble I find that Girard-Teulon, Lefort, says in Meyers' work on the eye, that "the constant current has been recommended for the rapid absorption of these opacities," but the constant current is negative Later, in the Philadelphia Polyclinic of April 24, 1897, Dr de Schweinitz of Philadelphia insists upon the value of faradization of the eye in interstitial keratitis If it is good in keratitis of this character, why not use it in choroiditis, as we know that the cause is the same in both troubles? In fact, many writers claim that keratitis is dependent entirely upon syphilis I do not claim to say that in connection with these absorbents which I have mentioned, electricity will cure all choroidal troubles I want to say in justification of my position regarding the treatment of these cases, that I have used electricity for the past three years and in the past few months I have given this treatment a thorough test, and we can not get anything that will substantiate us like living facts In conclusion, I will report three cases which I have had in the last eight months, as follows

Case 1 —A lady, 55 years of age, had been treated for about twelve months before she came into my hands She told me that she had taken iodid of potassa in very large doses almost the entire time, also strychnia, and that she had gone blind during this time I examined her with the ophthalmoscope and I *found that the vitreous was literally full of floating* bodies, and the fundus oculi could not be discerned at all The vision in the right eye was light perception only, in the left she read sixty feet type at 30 inches I could get no history from her case that was worth anything at all to me, she was a strong, seemingly healthy woman, had never had any eruption on the body at all I told her that I would give medicine internally and apply electricity to the eyeballs externally She at once objected to this and said she was afraid of electricity, I tried for several weeks with the internal treatment, when I had increased the kali iodid to 50 grains three times a day and the bichlorid hydrargyri to $^{1}/_{20}$ grains three times a day She got no better, but grew worse I then insisted that she allow me to apply the electricity, to which she finally consented, as I refused to treat her longer unless she would abide by my directions In her case I commenced giving her the positive pole faradic current, from five to eight cells, in each eye five minutes daily through a wet sponge Within a week's time she began improving, I kept this up for four months, at the end of which time her vision had gained in O D V $=^{15}/_{120}$, in the O S V $=^{15}/_{60}$

Case 2 —A Mr R, aged 30 years, eyes had been failing for several months Diagnosis choroiditis, syphilitic, although no *history of syphilis I found* with the *ophthalmoscope* that the vitreous was literally full of floating bodies, his vision in the O D V $=^{15}/_{200}$, O S V $=^{15}/_{60}$ I put him on kali iodid, 20 grains three times a day and increased it *until he reached* 60 grains three times a day, and bichlorid $^{1}/_{30}$ grain per day, increasing the doses until I gave him $^{1}/_{15}$ per day I also gave him the faradic current (eight cells) in each eye five minutes every day At the end of one month's treatment his vision was O D V $=^{15}/_{20}$, O S V $=^{15}/_{40}$, and he thought he was well enough to quit and went home

Case 3 —A man aged 30 Seemed to be in fair health, with no syphilitic history, ophthalmoscopic findings the same as the former case—the O D V $=^{10}/_{120}$, O S V $=^{0}/_{120}$ He gave this history His eyes had been failing for two years and he had been treated for months during that time without any benefit, but was gradually growing worse until his vision was growing so bad that he was almost compelled to give up his business, being a merchant I put him on the kali iodid and bichlorid in increasing doses as in the former cases, with a faradic current of eight cells applied to each eye every day In the meanwhile he told me, after taking the first dose of my medicine, that he had been taking this medicine and that he had no confidence in it, as he had tried it for nearly two years I asked him if he had had the electricity applied to his eyes before He replied, no I told him that we would watch the case for fifteen days, and if he was not improved by that time that I would not advise him to continue the treatment, at the end of that time, however, he had gained about 25 per cent At the end of two and a half months his vision measured O D V$=^{15}/_{60}$, O S V $=^{15}/_{20}$ He was dismissed, as he thought he had vision enough to get along with very nicely

I have reported three of the latest typic cases of this kind that I have had, but I could give you twenty cases, if necessary, in which this treatment has proven to be just as effectual as in the three cases I have reported

DISCUSSION

Dr F T ROGERS, Providence—I question the advisability of discussing the use of electricity when quoted in such indefinite terms as the writer of the last paper uses To say that you used twelve cells does not mean anything You may have a cell of 4 milliampères or one of 15 The milliampère is the important feature and not the number of cells used I have *used the galvanic current on my own eye as a matter of exper* iment and I find that 3 or 4 milliampères is all I care to stand Such generalities are worthless in a scientific report

Dr J E Minney, Topeka—Not knowing anything about the subject I may be able to give you some information It struck me the Doctor gave larger doses of anti syphilitics than the other fellows and that there was the secret of his success

Dr C E Norton, Lewiston, Maine—I do not know any thing about this subject but rise to make inquiry of the reader of the first paper I did not understand the direction in which he inserted the needle in his operation for pterygium I think, too, I understood him to say that he used the positive pole and got bubbles of gas around the needle According to my experience in electrolysis this would not be true, it would be the negative pole that gave the bubbles of gas, and the needle after having used this current would be extracted with some difficulty, as it would be held firmly by the hardened tissues

Dr Leartus Connor, Detroit—I have used electricity in a few cases of choroiditis, but I was not able to determine that it had any appreciable effect upon the course of the disease I am glad that somebody else has had success Possibly my method of using it was faulty I have not used electricity in the treatment of pterygii, but I shall be induced to do so by Dr Starkey's experience

Dr George M Gould, Philadelphia—My friend, Dr Alleman of Brooklyn, N Y, was several years ago interested in clearing up corneal opacities by electricity I visited him at about that time and he was very enthusiastic in showing me several cases that had greatly improved in vision On a visit there last year I asked him if he was still keeping up this treatment He said no, that the patients got very tired of the treatment before much could be accomplished, and gave it up through lack of patience and perseverance I believe he never applied more than two or three milliampères at one time

Dr R L Randolph, Baltimore—I would like to ask what experience the gentlemen have had in the use of electricity for removing eyelashes? My own experience is that it is painful and in many cases fruitless

Dr Melville Black, Denver—Some few years ago I read a paper wherein the writer describes the effects of the negative pole of the galvanic current for reducing tension in glaucoma I tried it on a few cases and think in one or two I could see an appreciable reduction In several other cases there appeared to be no action whatever and it was a waste of time For the removal of eyelashes the method is satisfactory enough if you can keep the lids quiet, but that is hard to do

Dr T A Grigg, Butte, Mont —I have had quite a little experience with the electric needle in removing cilia and wild hairs In some of my cases the results have been very satisfactory and in others not so much so In one case of wild hairs it seemed to me that for every one I killed two came to the funeral I usually find that by using 5 per cent cocain solution applied to the lids on absorbent cotton and then using a fine needle with a stop on the handle so that you can keep the lid still by drawing it up while the current is being turned on I get very good results I use a magnifier to see where the needle is going in and have the patient hold the sponge in the hand corresponding to the same side being operated upon In a second or two I get a few bubbles, and then with a pair of cilia forceps I can easily extract the hair If it does not come easily it will generally recur, and it takes a good while to make a complete cure

Dr J O McReynolds, Dallas, Texas—With regard to the question asked by Dr Randolph I have had considerable experience but I have not used this method so much during the last three years as I did previously My main reason for discontinuing it was the intense pain produced The operation can be perfectly successful in removing the cilia and they will not return if thoroughly removed My method is to have the patient hold the positive pole in one hand and steadying the head I insert the needle well down beside the hair turn on the current gently and wait until the bubbles rise round the hair, when I can pull it out with my fingers If the hair is still sufficiently firm to require forceps it will generally recur The bubbles will always appear if the needle is in the hair follicle

Dr Grigg—Can you always remove the hair with the fingers?

Dr McReynolds—Yes, if I have done the work properly The smaller the hair, of course, the greater the difficulty in removing it

Dr J L Thompson, Indianapolis—I reported a case some years ago in Knapp's Archives, which I might refer to to impress upon you the importance of using the positive pole It was a case of cure when I knew nothing about the use of electricity and I must say my method was a good bit like operating upon a cataract with a nail

Dr Hinckley—I use a 20 per cent solution of cocain, with 10 per cent carbolic acid, inject about 2 drops, and have no pain in removing lashes

Dr H M Starkey, Chicago—At the outset of this paper I thought to make a brief review of the general uses of electricity but later concluded it must be restricted to three things, the use of electricity in trichiasis in ocular neuralgia and in pterygium, and finally it was found that the latter alone would take all the time given for the paper

It is well known that it had been recommended to use the negative pole in glaucoma I can see a rational reason why the negative pole, which through cataphoric influence tends to withdraw fluids from the tissues should lessen tension, and I can readily see how by reversing the current we might in some cases favor glaucoma Especially in elderly people have I on this account been careful in the use of electricity

As to the question of gas appearing at the positive pole, we know where the gas comes from when electrolysis is used If the poles be placed in water decomposition of the latter occurs, hydrogen appearing at the negative pole and oxygen at the positive—twice as much, however, of the former as of the latter When the platinum needle is used and the current concentrated at the point we get a liberation of gas through decomposition of water and the tissue salts at that point and may have corrosion of the needle

I have used the negative pole in some cases to assist in dissolving off cicatrices In these cases of corneal opacities we use the negative pole, because we desire its dissolving action The first case I used it upon was a man, who, through an explosion, had lost one eye, and the other seemed to be in a hopeless condition By using 1 or 2 milliampères at a time for a period covering the greater part of a year, sufficient vision was secured that he was able to do a certain amount of work and later he became a gatekeeper at the shops where he had formerly worked He could also read coarse print I have not used it very much of late, but would again in a similar case to that

The direction of the needle in operating upon pterygium is at right angles to the growth or in other words it is passed in the same direction that the knife is passed in an excision

Dr R L Le Mond, Denver—I felt almost sure that I would not have a great many to agree with me on this paper and I am sorry that Dr de Schweinitz is not with us, for he has given this subject much attention and claims that it has been very beneficial in his hands

I have used the potassium iodid and the bichlorid of mercury in a number of cases without any practical results at all, and in one of these cases I used it until the patient continued to grow worse, and saying that she had gone blind under the identical treatment and had no confidence in it I put her on electricity I used the faradic current and she began to improve at once

I do not think we understand as much about electricity as we should In galvanism one pole is negative and the other less so while in faradism one pole is positive and the other less so That is the difference in the two kinds of electricity As regards the number of cells, I understood the instrument maker that each cell represented 5 milliampéres

PHLYCTENULAR KERATITIS

Presented to the Section on Ophthalmology at the Forth ninth Annual meeting of the American Medical Association, held at Denver Colo, June 7-10 1898

BY DUDLEY S REYNOLDS, A M, M D

Professor of Ophthalmology, Otology and Medical Jurisprudence in the Hospital College of Medicine, Medical Department of the Central University of Kentucky Surgeon to the Eye and Ear Department of the Louisville City Hospital, Surgeon to the Gray Street Infirmary, etc

LOUISVILLE KY

At the meeting of the AMERICAN MEDICAL ASSOCIATION in 1893, I had the honor to introduce the subject of phlyctenular ophthalmia My paper elicited extended discussion, embracing many divergent views both as to etiology and treatment The result of that discussion determined in my mind the necessity of more painstaking observations For reasons beyond my control, I was not able to begin my work until August, 1894, and I am now indebted to the painstaking labor of my friend, Dr Travis A Bullington, for the first part of what I intend to be a continuous series of observations concerning the nature, causes, and the treatment of phlyctenular ophthalmia

The first series of observations by Dr Bullington, and which I have the honor now to present for your consideration, is taken from my clinical record at the Hospital College of Medicine, beginning August 25, 1894, and extending through the first one thousand names on the list at my clinic These persons have been kept under observation for a period of three years, ending August 24, 1897

CASES OF PHLYCTENULAR KERATITIS

Occurring in one thousand consecutive names on the Clinical Register of Prof Dudley S Reynolds at the Hospital College of Medicine, Louisville, Ky, beginning August 25 1894, compiled by Travis A Bullington, M D

No	Age,	Sex	Race	Present Complications	Recurrent Conditions
1	19	M	C		Phlyc conj

41	3	F	W		
42	35	M	G	Phlyc conj	
43	30	F	W		
44	18	M	W		Phlyc conj et eczema nasalis

There are in this list 44 cases of phlyctenular keratitis In 12 of these cases phlyctenular conjunctivitis coexisted at the time of registration In 14 of the cases phlyctenular conjunctivitis subsequently appeared at varying periods of two to twenty-seven months from the date of the first attack In but 3 of these people did keratitis reappear In 5 eczema nasalis was present as a complication at the beginning In 2 other cases it appeared subsequently In 5 persons blepharitis marginalis was present as a complication in the beginning In 3 other persons blepharitis marginalis occurred subsequently In 1 case iritis, with phlyctenular conjunctivitis, appeared twenty-one months after the phlyctenular keratitis In the whole 44 persons not one received any local treatment, whatever, during the continuance of the phlyctenular keratitis The greatest period of treatment extended through three weeks, the shortest period five days In every case bichlorid of mercury, and sulphate of quinin were relied upon, with such additions as were suggested by complicating states of the patient's general health, constipation being overcome by saline aperients, and by regulation of the diet and habits of the patient Those cases amenable to discipline, and which could be traced after a lapse of three years' time, are alone included in the table Happily there are no more than three in the list of a thousand persons which had to be eliminated from Dr Bullington's record

Under the head of recurrent conditions, will be found diagnosis in each case, on subsequent return to the clinic after recovery from the first attack In every case lymphatic engorgement, or other manifestations of the strumous diathesis were present Blepharospasm and photophobia were often relieved by a single dose of Rochelle Salts or an antiperiodic dose of sulphate of quinin A child of from seven to fourteen years of age, after an aperient, may take a single dose of 10 grains of sulphate of quinin, with marked amelioration of the condition of the eye The subsequent treatment should include both mercury and sulphate of quinin, in minute doses For a child under ten years of age, 1/10 gr of sulphate of quinin, and 1/50 gr of bichlorid of mercury may be given together every hour, every two hours, or every three hours, according to the intensity of the blepharospasm and photophobia Above ten years of age, ½ gr of sulphate of quinin should be given with 1/50 gr of bichlorid of mercury, every hour, every two hours, or every three hours, according to the urgency of the symptoms

Eczematous eruptions of the face and scalp yield readily to the application of ammoniated mercury Similar eruptions in the anterior nares are relieved by a mixture of yellow oxid of mercury ointment, and liquid pitch, whilst mucopurulent inflammations of the Schneiderian membrane demand the use of sprays, the best of which contain bichlorid of mercury, and chlorid of sodium Where a tendency to inspissation of accumulating matters in the nasal passages exists, a powder composed of borate of sodium ½ ounce, chlorid of sodium 10 gr, camphor 15 grains may be advantageously employed as snuff frequently during the day Children under 12 years of age, however, are not likely to use the snuff, in such cases an aqueous spray of borate of sodium 2½ drachms, chlorid of sodium ½ drachm, distilled water 8 ounces, camphor water and mint water, each 4 ounces, carbolic acid in crystals 4 grains This mixture makes a most agreeable spray, and is valuable not only as a cleansing fluid, but is soothing and agreeable to the sensibilities of the patient, and the child which at first rebels at the spray, will usually in a day or two, not only yield without contest, but often seek the application

To sum up, I wish to say that Horner's notion of the relations existing between eczematous eruptions of the skin and anterior nares to the phlyctenular diseases of childhood is not always apparent, but nearly constant The conditions which predispose to these local disturbances are essentially constitutional, and no local treatment is, in any large proportion of cases, to be regarded with favor Per contra, constitutional measures are of the first importance, and may alone be relied upon, even in complicated cases, so far as the eye is concerned as a participating organ

DISCUSSION

Dr C R Holmes, Cincinnati—I am very glad to have heard this most excellent paper We all know that unless we treat this class of cases as Dr Reynolds has outlined it, the results are not very satisfactory We have all of us had cases come from very good men who treated them without any results because they neglected the nose and the constitutional symptoms and relied too much upon local treatment I have been following for several years the same routine treatment, though using perhaps a little more local treatment than Dr Reynolds called attention to, and I also like to use in this class of cases a weak solution of eserin, with cocain I do not use atropia except in rare cases I use eserin, $\frac{1}{10}$ of a grain to $\frac{1}{2}$ ounce, and a 2 per cent solution of cocain, having it instilled into the eye two or three minutes before the salve is applied, because the cocain will enable the parents to put the salve in better than they could otherwise do

Dr J L Thompson, Indianapolis—This paper is much more valuable than a consideration of 500 cases of cataract operation In our section of the country we have phlyctenular keratitis from spring until late October This is especially so with children, and I find that constitutional treatment is above all others If the patient can stand it I have them change climate, make a trip to Bayview or Petoskey It is astonishing, also, how a change of diet helps With a correction of diet, and after three or four days of a changed climate they report favorably, while if compelled to keep them in Indianapolis they hang on for a long time

Dr T A Grigg Butte—Do you ever notice that these elevated spots on the eye sometimes break down to form ulcers?

Dr Thompson—Yes, frequently, and if they stay in a hot climate they will persist for a long time

Dr Boyd—We have with us a great deal of this disease, and I want to say one thing in the line of treatment We are always compelled to use quinin I think we always have in these cases some malaria, and quinin and arsenic should be used in the treatment I should think the use of eserin or atropin would depend upon the location of the phlyctenular We ought to be very careful as to the use of cocain in our treatment and if used it should be in very small doses

Dr E C Ellett, Memphis—I come from a district that is very malarious, being low and damp, and I would not give much for anybody's diagnosis of a malarial condition unless it is confirmed by an examination of the blood While we give small doses of quinin, it is done as a tonic, and I should like to know whether or not these gentlemen have verified their diagnosis of malaria by examination of the blood and, if so, what form of the organism they found Dr Ziegler once said before this section, "No tea, coffee cakes or candy,' and that comes mighty near covering the things in diet that should not be allowed

I do not see many cases of phlyctenular keratitis or conjunctivitis that run a course of three or four weeks, most of them being over in one week With regulation of the diet, attention to constitutional treatment and the local use of the yellow oxid ointment they get along very nicely I have seen a great many cases of this trouble among negroes we can not send to another climate Those practicing ophthalmology in the south know that corneal troubles are particularly common among this race, and this disease is especially common among negro children

Dr Leartus Connor, Detroit—As bearing upon the remarks of Dr Thompson it occurs to me to report that in Detroit we have very few cases of phlyctenular disease and very many less since our Island Park was opened some seventeen years ago It is an island of 700 acres in the center of the Detroit River, and children of families in moderate circumstances are taken there in large numbers and very frequently It is for them a Petoskey or Bayview A point that occurs to me is that the keeping of those children out of doors as much as possible has aided materially in their improvement, and another observation along the same line is that in our children's hospital, which is one of the most perfectly lighted and ventilated buildings that I know of, the children recover from this affection in a very small fraction of time compared to what the same case would do in the private home There the children are so cared for as to be made happy, whereas in most of the homes they come from the mental depression produced by the surroundings is disturbing to the reparative process

Concerning the local treatment, while in former years I used eserin and am not entirely opposed to it now, I find that the use of atropin seems to be more satisfactory in allaying the pain and irritation, so I have almost stopped the use of eserin and cocain

If we could make the conditions of child growth anything like what they ought to be these cases would not occur

Dr H B Young, Burlington—I agree with what Dr Connor has said and with what others have said concerning the constitutional treatment, but we should not overlook the blood making qualities of small doses of calomel I have found more benefit from the use of this drug in small doses than from any other treatment Of course, properly speaking, mercury is not a blood maker, but in these cases we have a condition of mal nutrition, with poor digestion, and the intestinal secretions are interfered with in some way or other, so that small doses of calomel, avoiding the cathartic effect, bring about rapid improvement

As to the use of the yellow oxid ointment most of your prescriptions bring forth a preparation that ought never to be put between the patient's eyelids, and it is due to the imperfect method of making it I usually prepare mine myself I take the yellow oxid, put it on a slab with my menstrum, white vaselin, and mix them, rubbing it and rubbing it with a spatula, always allowing the spatula to clean itself by continued rubbing, and I get a smooth preparation

Dr Melville Black Denver—We do not see many cases of phlyctenular keratitis in Denver, but we are not free from it One thing I have noticed is, if pains be taken to trace the cause, that these children are universally spoiled and have been allowed to take anything they pleased to eat and to drink coffee and tea at a very early age I believe that bad feeding is responsible for nearly all the cases we see

I want to call attention to a very nice base for the yellow oxid ointment, known as cold cream or rose water ointment It is as you know, an emulsion of white wax and rose water with a small amount of oil It is better than vaselin alone because it mixes more readily with the tears and does not flow out of the conjunctival sac It is harder and does not [illegible] in summer as does vaselin

Dr J L Hiers Savannah—I listened to [illegible] paper with interest because I come from a malarious district where we have a great deal of such troubles, and I heartily indorse the constitutional treatment outlined, but I would like to add something to the local treatment It is my custom to give the yellow oxid of mercury ointment before the phlyctenular breaks, but after it breaks down I treat the ulcer with iodin My mode of application is to cocainize the eye thoroughly, scrape the ulcer with a spud and apply the iodin on a small cotton tipped probe After this I wash the eye with saturated solution of boracic acid and to overcome the reaction as much as possible and set the eye at rest, a good sized pledget of cotton is saturated with this solution and applied to the eye with a bandage The eye is kept closed for from six to twelve hours and I rarely find it necessary to use atropin My first experience with iodin in the treatment of corneal ulcers occurred about three years ago and I find that it seems to destroy the germs and convert the ulcer into a healthy wound

Dr Flavel B Tiffany, Kansas City—I have had a great many cases of phlyctenular keratitis in my practice I very rarely go to my clinic without finding one or two cases of this disease I have never regarded these cases as being of a malarious nature, but rather as being strumous You always find them among the poorer class of people and often in the offspring of syphilitic parents I never use quinin in the treatment of these cases, nor do I think as a rule it is indicated Phlyctenular keratitis is not ulceration of the cornea, it is papule not pustule The phlycten contains a fluid and that fluid probably contains a specific bacteria, I believe it is claimed by some that they have found the specific germ Mercury not only acts mechanically in rupturing the phylcten, but it acts further as a germicide I also use atropin and cocain but as systemic treatment I rely almost entirely upon the syrup ferri iodidi, with cleanliness, good food and good air

Dr R F LeMond, Denver—Dr Reynolds was my first teacher on the eye and I always love to hear him talk for he always means something

I believe that this trouble is due very largely to malnutrition and lymphatic engorgement Invariably they occur in children whose parents are not strong and I think it would be irrational to treat these conditions without resorting to constitutional remedies I practiced medicine in Texas a good while and saw much of this trouble there I found the children suffering with general engorgement of the whole lymphatic system and if that is corrected by small doses of calomel and they then be put on a good tonic like iron, quinia and strychnia, the phlyctenular trouble soon disappears For local treatment I prefer a wash of 1 to 15,000 or 1 to 20,000 bichlorid, to be followed by a saturated solution of boracic acid If the phlycten is trying to mature into an ulcer I use atropia unless I see some chance of cyclitic engorgement Eserin often acts nicely in these cases where there is much photobia

Dr J O McReynolds, Dallas, Texas—It seems to me the discussion has taken a turn that is exceedingly important, and I feel that I ought to emphasize the remarks made particularly by Drs Thompson and Conner regarding the sanitary condition of the patients My own experience has been that we have only a little phlyctenular trouble in Dallas, and when we do have it I seldom see a case that is obstinate I have noticed that there was a marked contrast with the large amount of phlyctenular troubles in other cities, and I attributed it to the fact that we have a salubrious climate where the children live out of doors a great deal All of the recognized forms of treatment, it seems to me, are entirely satisfactory in Dallas, for the cases generally get well in a few days with different forms of treatment

Dr J E Minney, Topeka—I thank Dr Reynolds for this practical subject It is almost invariably our practice to give 1 grain of calomel in ten tablets, one of these to be taken every hour, and in addition we dust the phlycten with the mild chlorid and it disappears like snow before the morning sun Respecting the blood making power of calomel, I think it has been pretty well demonstrated that in 1/10 grain doses, given three times a day, it will increase the red blood corpuscles

I am very much pleased to learn how to make the yellow oxid ointment We have in Topeka a hundred druggists, and perhaps three or four make it properly

Dr W C Bane, Denver—It is my habit to order the oxid of mercury rubbed up with a drop or two of olive oil, then with lanolin or vaselin

Dr C E Norton, Lewiston, Maine—In our country we have no malaria, so that can not be a cause for our phlyctenular keratitis We use quinin in the State of Maine only as a tonic, unless our patients have come there from a malarious region The majority of the cases I have had occurred among the poorest children in town, who did not have proper nutrition The question of what should not be given has been brought up, but nothing was said about the kind of food the children should take One of my instructors, Dr C R Agnew, used to prescribe the food the children might take, and it consisted of bread and milk

As to bandaging the eye, it seems to me that is bad treatment I am careful to do all I can to get the children to open the eyes, and for this reason I believe that cocain is of sufficient benefit to counterbalance its destructive influence upon the cornea

Dr R L Randolph, Baltimore, Md —In all forms of keratitis, especially the phlyctenular variety, we have irritative symptoms In phlyctenular keratitis we have exposure and inflammation of the nerve endings and as a consequence spasms of the accommodation and contracted pupil It would seem that eserin in such cases would only intensify this condition Complete rest of the accommodation and removal of the irritative symptoms is demanded, an end which is best obtained through atropin The more he employs eserin the more he is convinced of its very limited usefulness outside of its value in glaucoma

Dr Reynolds—I am very much complimented by the character as well as the amount of the discussion In a brief paper a man can not bring out all the points he might consider essential I am so well known as a crank on the subject of foods and digestion that I refrained from mentioning much that I perhaps should have said on this subject I believe, as Dr Norton said, that when we have to deal with a case that is badly fed and wants to eat sweet things, which I always forbid, that a diet of bread and milk is best for the child I frequently prescribe alternate cupfuls of malted milk and beef tea, and I prefer the Armour extract of beef because I find it of uniform quality and reliable strength I am one of the few that believe in beef tea for its nutritive value and do not consider it as merely a stimulant I insist that the child should have plenty of pure water and fresh air and if it buries its head in the pillow it is all the more reason why it should be taken out of doors I give the mercury not because it makes blood, for I know it does not, but because it relieves the engorged glands, and I use quinin, not because of any malarial condition, but because it is a reliable stimulant of the emunctory organs It is more reliable and less debilitating than any other sudorific and diaphoretic known to me

---

Adenoid Vegetations—G Zimmermann attributes the etiology of recurring pseudo croup to adenoid vegetations, and states that in his experience, extirpation always cures the croup Bilhaut also emphasizes the frequency of curvature of the spine, scoliosis, kyphosis and lordosis in children affected with adenoid vegetations, and has observed all these troubles vanish after their removal He claims that this should always be the first step in the treatment of any defective development of the spine or thorax Lauffs has also recently reported the cure of a distressing case of prolapsus ani in a boy of five, cured by removal of his adenoid vegetations —*Munich Med Woch* , July 12 and 18, and *Vienna Klin Woch* , July 14

THE USE OF FORMALIN IN THE TREATMENT OF BLEPHARITIS

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo , June 7 10 1898

BY H MOULTON, M D
FORT SMITH ARK

During the past year I have employed formalin in all cases of blepharitis To apply it I use a tooth pick with a small cotton mop wrapped on the tip so that it does not take up enough solution to run into the conjunctiva The solution is made of the strength of 2 per cent to 1 per cent, beginning with the weaker It must be frequently renewed or prepared extemporaneously at the time of using, in order to insure uniformity of strength

The lid is drawn away from the eye ball The mop dipped in the solution is rubbed gently along the margin among the lashes until all the scales and crusts are removed and until the surface of any little pustule is rubbed off The site of disease is thus left clean and smooth The mop is renewed a time or two during each operation A little bland oil may be applied afterward, or the formalin may be used in the oil The applications are made daily if possible by the physician's hands Otherwise they may be made by the patient at his home

The correction of all retractive errors I hold to be of prime importance, likewise the improvement of local or general conditions which may predispose the margins of the lids to disease With these precautions taken, it is gratifying to note how rapidly patients will improve under formalin treatment It will invariably improve all cases and cure many of them Some of those cured will relapse, but a renewal of treatment again relieves them Several of my cases had been treated by myself by other means with little or no benefit, but improved rapidly under formalin

One, a school girl, had been under observation for six years She had been treated for two months by an eminent man in St Louis, and for various periods by myself with the full catalogue of salves and solutions, without result In one month under formalin the edges of the lids were smooth and white, and have remained so for four months, though the girl continued in school

Another case was that of a young lady whose blepharitis had produced a trichiasis, requiring the Hotz operation for its relief, the blepharitis having been previously cured with formalin From January to the present writing her lids have remained well Other agents than formalin had proven valueless

A clergyman, aged 27, had worn glasses and been treated for many years for blepharitis without a month's relief A month's use of formalin left his lid margins healthy They remained so from July, 1897, till April, 1898, when with over-use of the eyes he suffered a relapse, which again yielded promptly to formalin

Some cases do not seem to get entirely well for longer than a few days but the use of the formalin is so effective in keeping the disease in check that such patients are glad to keep up its use by their own hand I do not wish to say that I have not found benefit in many cases from the use of other drugs or that formalin is a permanent cure, but the proportion of cases benefited and the measure of relief afforded by this remedy is so vastly superior in my hands to other remedies, that I cannot do otherwise than call attention to it

AN UNUSUAL CASE OF RUPTURED TUBAL PREGNANCY, OPERATION AND RECOVERY

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY J E COWLES, M D
LOS ANGELES CAL

This case of tubal pregnancy is worthy of record on several accounts First, because of its early rupture, being but about four weeks advanced in pregnancy, second, because of recovery from such a dangerous state of collapse as occurred during the operation, and third, on account of the severe complication—left lobar pneumonia—which set in on the second day after the operation, and would seem to have barred what little chance of recovery was still left to the patient

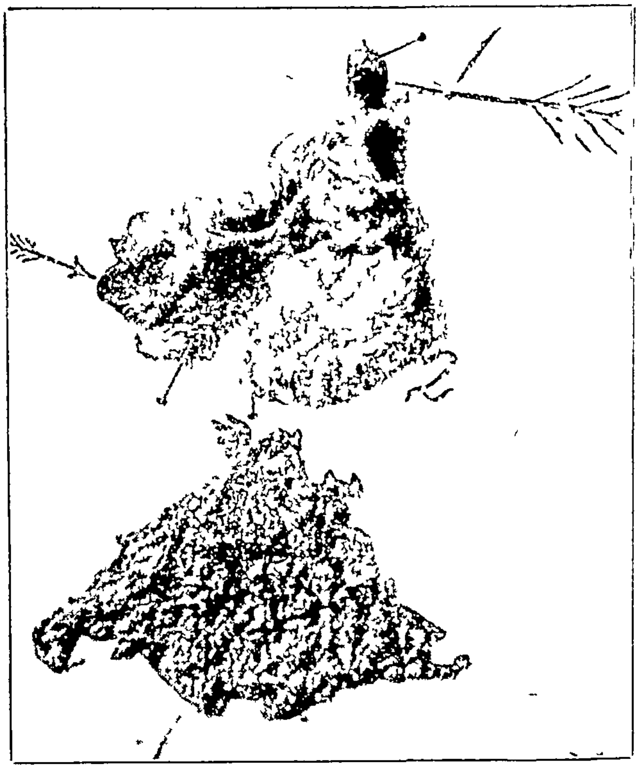
Mrs M L J , American, age 30, married seven years, mother of two children, never had a miscarriage, abortion or any serious sickness before this, but was delicate in childhood Began to menstruate at 15 years of age and first suffered severe pain with her periods at 17, which *continued until after the birth* of her first child, when the pain lessened in duration and severity, lasting only during the first day, where previously it had continued two or three days Has always been fairly regular, but on several occasions went over a week, and once last inter ten days Her last period, before this accident, began n January 20 and continued for a week as usual During February she felt well, no nausea or other symptoms of pregnancy being noticed, except swelling and tenderness of the breasts, which always occurred as her menstrual period approached, and consequently did not impress her as auguring anything unusual On March 1, 1898, at 10 30 A M , while sweeping a room, she stooped, and while in that position was seized with a severe pain I saw her at 2 P M and observed her ghastly pallor and look of distress, not a particle of color in cheeks or lips, pulse 110 and thready, respirations rapid and shallow, temperature subnormal, abdomen very tender and the patient evidently suffering exquisitely I gave hypodermically a combination of atropia and morphia containing a quarter of a grain of the latter, and repeated the dose in half an hour, no relief having been experienced This making the pain tolerable, I left 1/10 grain morphia to be given every hour until my return I returned at 5 30 P M and gave another 1/4 grain dose of morphia hypodermically, the pain continuing atrociously severe, being steady rather than of a spasmodic character Bimanual examination revealed nothing of a positive nature Being satisfied that a severe hemorrhage had taken place thinking that it came from a ruptured tube, counsel agreeing with me, I proposed operation for an early hour next morning, but the patient declined, until her mother could arrive that night Accordingly, at 8 o'clock the following morning, a celiotomy was done in the patient's bedroom, with the best antiseptic precautions available, but with the dangers and difficulties usually attending operations in private apartments, not the least of which, from the patient's standpoint was a cold room

The recorded temperature of patient at 6 A M was 96 6 degrees F with pulse at 118, small and thready, although fortified beforehand with strychnia and digitalis

Patient being etherized, I made a three inch incision in linea alba just above the pubes On reaching the peritoneum it pouted into wound and showed dark underneath On opening it dark blood squirted upward several feet A quart or more of liquid and clotted blood was removed and a rupture in the right tube, close to uterus was discovered After tying off tube and ovary on right side, the left was brought up examined, found healthy and dropped and the toilet of peritoneum about completed, when considerable oozing of blood from stump and broad ligament was noticed Great difficulty was experienced in controlling it final resort being had to the cobbler stitch with catgut Abdomen was closed without drainage the peritoneal cavity having been filled with normal salt solution When the operation was completed, the patient was in extremis, with a pulse of about 180 and almost imperceptible at wrist

By the aid of hypodermics of strychnia, atropia, digitalin and nitroglycerin given to the limit of safety and enemas of hot salt solution, coffee, whisky and aromatic spirits of ammonia, the patient reacted and at 6 P M exhibited a pulse of 138, of fair tone and volume and a temperature of 100½ degrees F , respirations 30 March 4, 6 A M (next morning), pulse 120, temperature 100½, respirations 30 , March 4, noon, pulse 122, temperature 101½, respirations 30 , March 4, 3 P M , pulse 140, temperature 102⅘, respirations 32 , March 4, 10 30 P M , pulse 137, temperature 103⅕, respirations 36 (At this time the decidual membrane shown in the photograph appended was expelled from the vagina, no shreds or bloody discharge being noticed before)

March 5, 6 A M , pulse 136, temperature 102½, respirations 38 with some cough. Examination revealed crepitant râles at base and posterior part of left lung From this date to the 14th as a complication of the already serious condition, there was a typic left lobar pneumonia, the pulse gradually coming down to 118, at which it stood on the latter date After March 14 there was practical defervescence, with the patient rapidly improving in strength and looks About this time every alternate suture was removed from the abdominal wound and the balance a week later No suppuration or trouble of any kind occurred about wound or sutures, silkworm having been used externally and the patient was sitting up in three weeks from date of operation



1 Fimbriated extremity of tube 2 Ovary 3 Point of rupture of tubal pregnancy 4 Decidual membrane surface of attachment to uterine wall

April 22 her period reappeared with the usual pain and lasted a week May 7 inspection of the abdomen revealed a firm scar, two and three fourth inches in middle line just above pubes and natural contour of the abdomen Bimanual examination shows uterus of normal size, slightly anteflexed and freely movable *without pain* May 23 began a repetition of pain and period with usual length of flow The specimens being hardened in formalin solution, were submitted to Dr Stanley Black, pathologist, to whom I am indebted for a careful examination, and who reported the following I have examined the specimens, find chorionic villi in the Fallopian tube and decidual cells in the membrane

I append a photograph showing the specimen before mutilation No 1 points to the fimbriated extremity of the tube No 2 is the ovary, apparently normal in every way No 3 indicates the point of rupture, and just above No 4 is seen the decidual membrane, presenting its shaggy surface of attachment to the uterine walls

If I may be allowed a few observations in regard to this case, I will recall to your attention the fact that from the last day of menstruation, January 27, to March 1, the day of rupture, is but twenty-nine days From quite a search of the literature of these early cases, I have been unable to find a case of so early rupture as this, though I doubt not for an instant they may have occurred even earlier One of the earliest cases that I have run across is one of five weeks reported by Tait, in which death occurred in seven and one-half hours from hemorrhage, the rupture, as stated by him, from which the fatal hemorrhage took place not being larger than a pea As diagnosis and treatment are the most important considerations in all pathologic conditions, they are practically the only ones in this class of cases If one waits for a classic array of symptoms and refuses to operate until such an array is present it is my opinion that the patient is to be commiserated on account of her too conservative (?) medical attendant Dr Henrotin says "The diagnosis of primary complete rupture prior to the seventh week is the diagnosis of intra-abdominal hemorrhage "

Given a woman just previously in a state of health within the child-bearing period, with the physical signs of internal hemorrhage and the characteristic pains, if she be conscious, even though no coincident signs of pregnancy exist, I maintain that the medical attendant is not only justified in, but criminally negligent if he refrains from, operating (i e, making an exploratory laparotomy), thus increasing the woman's chances of recovery and demonstrating true conservatism, the conservation of life, always premising a fair degree of skill in the operator and a strict adherence to the details of asepsis and antisepsis Dr E S Boland of Boston in an excellent article on this subject "from the standpoint of the general practitioner," courageously remarks "although I have never performed a laparotomy, I should not hesitate to attempt it if I met one of these cases so remote as to require many hours to get greater skill," and concludes, "that prompt laparotomy after rupture is the only safe and conservative course " I think in a case such as the one reported, where the time on the operating table should be as short as possible, that it would be better to quickly remove the hematoma and bring together healthy surfaces with continuous catgut sutures, not removing tube and ovary if not otherwise diseased, and thus save an amount of added shock that might prove fatal It goes without saying, that the interests of such cases as this are better conserved in a hospital or sanitarium, for I am sure that the pneumonia here reported resulted from the too cool rooms, and the danger of transportation thither will no doubt be doubly compensated to the patient by the better operating facilities and comforts there to be had

As to the frequency of these cases compared with those of natural pregnancy there can only be surmise One author reports from his own experience 1 in 170 cases of normal pregnancies, while another reports 1 in 1500 cases Again, as to which tube is most frequently impregnated, that is, I dare say, purely a matter of accident, but I have noted in my search for these cases that it has most frequently occurred on the right side, and merely record the fact without attaching significance to it When we consider the large mortality of these cases if left to nature or medication (see Baldy's report of Formad s autopsies) and the brilliant results obtained by the early operation, we are constrained to recommend the rule When in honest doubt, operate In a letter dated April 22, 1898, Dr M D Mann of Buffalo, N Y, writes me "I have operated forty or fifty times for that condition, four times within the last three weeks, and so far all have recovered except one, which was operated on through the vagina " This brings up the question as to the choice of route by which to reach the diseased condition In *recent* cases my own choice is for the abdominal route, as giving one absolute control over hemorrhage and enabling him to see all that is to be seen and if vaginal drainage is desirable it can be easily added

---

THE INFLUENCE OF SEX ON DISEASE

Presented to the Section of Obstetrics and Diseases of Woman at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo , June 7 10 1898

BY LOUIS FAUGERES BISHOP, M A , M D

NEW YORK

Curiously enough, while the tendency in modern civilization is to eliminate the distinctions in the political and economic status of men and women, that of medicine has been to exaggerate the natural difference of the manifestation of disease between the sexes

The object of this essay is not so much to show how many as how few are the differences The influence of sex on the course of general disease is wholly a matter of soil and environment, that is, the disease is the same, with the same tendencies and possible terminations, but modified by the constitution of the person and not by sex Granted that individual constitution does affect the course of disease, we must determine whether its characteristics differ according to sex, or whether they differ among individuals regardless of sex To predict our conclusions it will be found that the course of general diseases is not affected materially by difference of sex, except in a few instances that are easily defined and pointed out Apart from variety of occupation and greater or less exposure there are few factors which alter the percentage of men and women who acquire infectious diseases Typhoid, typhus and the exanthemata affect the sexes equally

Mortality is indeed greater among males when pneumonia is considered, but that is undoubtedly due to the greater abuse of stimulants by men In diseases of the nervous system the effect of sex upon the form of disease is more marked Men are more liable to the structural diseases, especially sclerosis, while women are more liable to functional disease As notable as any is the predominance of Graves' disease among women Especially is this marked when we include in Graves' disease many cases of tachycardia in which the eye and thyroid symptoms are not markedly developed The inference is therefore justified that, barring pelvic disease due to organs belonging exclusively to women, and those nervous diseases traceable to the acknowledged greater instability of her nervous system, the manifestation of disease in woman does not differ markedly from that seen in man under similar circumstances Nor can it be said that the influence of the pelvic organs in one sex has a much greater tendency to reflex manifestation in distant organs than those of the other

The influence of sex on disease as depending chiefly upon habits of life is well illustrated in the case of cardiac lesions The quieter life eliminates much of the danger of strain In women, who, as a class do not abuse alcohol, there is less tendency to arterial disease, and to all those symptoms that follow arterial sclerosis In old age the factor of arterial degeneration is apt to be less marked In young women the tendency of the sex to chlorosis should influence diagnosis, prognosis and treatment of patients presenting cardiac and pulmonary or nephritis symptoms Thus in a young man, dropsy of the feet would be more readily thought to be of kidney origin than in a young woman

The tendency to specialism is to treat the male and female as separate species This is so grave an error that it has seemed worth while to point out that men and women have most points of physical constitution in common, with only those modifications necessary to distinguish sexual function The diseases of infancy are exactly the same in both cases, the cardiac, pulmonary renal, gastric and most general diseases are the same Nervous diseases are indeed modified by a higher degree of direct and reflex excitability of the nervous system, but rarely by any disease of the uterus or ovaries Indeed, the belief is well founded that neurasthenia and hysteria are often aggravated by local therapeutics directed to their cure

It can be stated on the authority of nearly all those competent to study epilepsy from the neurologist's point of view, that this disease is hardly ever cured by operation The uterine and ovarian element in the general diseases of women is largely, at the present time, the unnatural growth of distorted public opinion, that has been led to attribute many conditions to local diseases of women, that are, in fact, common to both sexes, or at least only modified by the natural difference in general physique and nervous organization The fact that women are more liable to functional nervous disease is not due to disease of the pelvic organs, but easily and wholly traceable to the physiologic difference of the general nervous system So the appreciation of the difference in the course of disease in individuals, of whatever sex, need only be modified, as it always is by the variation of constitution, whether between one man or another, or one woman and another, or between a man and a woman A woman leading a healthful outdoor life, with her muscles in use and her muscular tissue thoroughly active in its oxygen-absorbing and heat-producing functions, is more of a man in one sense of the word than the confined, undeveloped and anemic city clerk This difference in physical stamina between the sexes is not due to the influence of any set of organs, nor is it to be modified by any degree of health of these organs that can be attained independently of the rest of the body What small difference there is in disease is due to the minor difference in nervous irritability, but far more to the influence of habits of daily life

The influence of sex upon the course of internal disease is not therefore to any great degree influenced by sex, as such, but by the influence on disease of those external conditions which are common to both sexes, but which by custom may have come to predominate in one sex or the other Thus a woman is more protected from violent accidents, exposure to the weather and suffers less frequently from the results of alcohol, tobacco and some of the infections On the other hand, she is more liable to the evils of a sedentary and confined occupation, and the abuse of tea and sweets is much more frequent These circumstances are not n [illegible] ccom paniments of sex, because they are reversed in a great many individual cases

In the same way with character The female character and the male character, as composites of persons grouped by sexes are undoubtedly different, yet it is not a question of sex but of character So the course of disease in individuals is a question of constitution, not of sex

In therapeutics it will be those measures that most tend to overcome the deficiency of general vitality manifested in the circulation, nutrition and blood formation of women that will be most successful in removing the symptoms now so often referred to a trivial local disease that frequently, in itself, requires but little treatment The result of an impartial consideration of this topic leads inevitably to the conclusion that the influence of sex upon disease has been exaggerated, and that the great fundamental principles of physiology and medicine are the true supports of sound therapeutics in childhood and in old age, in men and in women

30 West Thirty Sixth Street

FALSE LABOR PAINS

Presented to the Section on Obstetrics and Diseases of Women at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo, June 7-10, 1898

BY T MITCHELL BURNS, M D
PROFESSOR OF OBSTETRICS, GROSS MEDICAL COLLEGE
DENVER COLO

As I believe there are important points in the diagnosis and treatment of false labor pains which are not mentioned by the majority of obstetric text-books, I desire to present this minor subject and obtain your opinions As we are called to our dispensary cases as soon as the pains occur every ten minutes, we have seen a proportionately large number of patients suffering from false labor pains At times calls to such cases have been nearly as frequent as to real labor

Synonyms —Premonitory pains, dolores presagientes, and, if you will allow me, threatening premature labor

Definition —False labor pains are pains which simulate true labor pains but are not at the beginning the result of compression or tearing of the nerves of the birth canal

Time —Generally in the last weeks of pregnancy, but they may occur any time during pregnancy or even in the non-pregnant to a less extent The pains frequently accompany sinking of the uterus or occur at the time for a menstrual period

Causes —Originally the cause is generally intestinal colic or some reflex local or peripheral disturbance Toothache is a peripheral disturbance that may result even in labor Rheumatism of the uterus, irregular contractions of the abdominal or uterine muscles, are given as causes In fact, any of the causes of abortion may produce false labor pains

Synonyms and diagnosis —It is said that none of the premonitory symptoms of labor are present Sinking of the uterus and other premonitory symptoms are often present A great majority of writers state that in a case of false labor pains the pains are irregular do not occur at the same time as the painful uterine contractions of pregnancy, that the pains are felt all over the abdomen and do not progressively increase as do labor pains, and that they do not dilate the cervix Now, this may be true at the onset, but sooner or later the pains may be only in the back or groins, occur regularly, be as severe as labor pains and often accompanied by painful uterine contractions which may cause from one to three fingers' dilation of the cervix

These uterine contractions are, however, generally only progressive for a time and disappear when the cause is removed It is sometimes impossible to differentiate them from true labor pains without waiting an hour or two to note the progress of the dilation of the cervix or the effects of the therapeutic test To determine if the uterus contracts at the same time as a pain, the text-books say to place the hands very gently to the fundus, but it may be necessary to feel the lower uterine segment per vagina to exclude the possible contraction of the abdominal muscles The symptoms of threatening premature labor are identical with those of false pains when painful uterine contractions are present A painless uterine contraction may occur at the same time as the colicky pain in the intestines The irritation caused by the colic may bring on uterine contraction, at first painless, later painful Effacement and one to two fingers' dilation of the cervix may occur in multiparæ, with lacerated cervices from relaxation, independent at least of painful uterine contractions

Prognosis —The pains generally disappear rapidly if the cause be removed Rarely premature labor follows Some cases of tedious labor supposed to be at term and lasting two or three days are probably due originally to the irritation of false labor pains which have produced enough irritation to excite a little prematurely true labor pains, and finally expulsion of the uterine contents When the false pains have excited threatening premature labor pains and some dilation of the cervix, labor at term is frequently easier as a consequence

Treatment —As soon as false labor pains are suspected a four quart enema should be given at once, and then a fourth of a grain of morphin hypodermically The morphin may be repeated by the mouth in an hour or two if the pain lessens but does not disappear Nothing stops the pain so rapidly as an enema Do not think of cathartics They take too much time and may increase the irritation In some cases it is impossible to stop the colic until after hot drinks, as ginger and peppermint, or inhalations of chloroform, and even hot fomentations and flaxseed meal poultices have been used

ILLUSTRATIVE CASES

Case 1 —Sinking of uterus and dilation of cervix to three fingers Physician remained all night because previous labors had only two or three hours' duration Just three weeks later patient confined, labor lasting only about two hours

Case 2 —Very severe bearing down pains, regular in frequency and severity, no dilation of cervix About one week later patient confined, pain not nearly so severe and bearing-down efforts less

Case 3 —Patient eight months pregnant, severe toothache last two weeks, last twelve hours labor pains, cervix dilated two fingers Morphin and chloroform given and tooth extracted The cervix closed Confinement one month later

Case 4 —Cervix dilated three fingers, previous slight pains absent One week later patient delivered after a few pains

Case 5 —Severe colic, no dilation or painful uterine contractions, enema, morphin, hot fomentations, flaxseed meal poultice and finally chloroform for over two hours before colic under control

Case 6 —Colic, enema and morphin not effective A teaspoonful each of tincture of peppermint and ginger in half a cup of sweetened hot water relieved

Case 7 —Patient examined at about the eighth month to see if placenta previa was present (Placenta previa complicated her last labor) Bag of waters found projecting through the effaced cervix dilated to two fingers

COLPOPERINEORRHAPHY AND THE STRUCTURES INVOLVED

DEDICATED TO DR THOMAS ADDIS EMMET AND MR LAWSON TAIT IN RECOGNITION OF THEIR LABORS IN THE SURGERY OF THE PERINEUM

BY BYRON ROBINSON, B S, M D
Professor in the Chicago Post Graduate School of Gynecology and Abdominal Surgery Professor of Gynecology and Abdominal Surgery in Illinois Medical College, Professor of Gynecology and Abdominal Surgery in Harvey Medical College Gynecologist to St Anthony's Hospital Consulting Surgeon to the Mary Thompson Hospital for Women and Children
CHICAGO ILL

Continued from page 594

The vaginal portion is endowed with considerable strength and it becomes blended with and is lost on the vaginal wall The rectal portion of the levator ani fascia superior passes to the rectal wall, becoming continuous with the fibers and blending with it There is a strong fillet passing between the rectal and vaginal canal The part of this fascia which passes to the rectal wall, has been termed the ligament of the rectum This fascia forms a strong support to the muscular wall of the rectum

It is not an argument very rich in facts to say that the perineal body is to fill in the space in that region It serves as an attachment for one end of the levator ani muscle A subject which I have not found mentioned in the books is that in many parts the fascia of the pelvis consists of many distinctly defined layers, which can be cleaved from each other For example, the fascia over the coccygeal muscle may be cleaved off in several layers, and the same may be said,—but not to such a degree—of the levator ani superior Several thin, transparent planes of fascia may be cleaved off of the obturator fascia superior Even the levator ani fascia inferior, which is very thin and compact, may be cleaved into two or more planes The obturator fascia inferior is a very powerful fibrous plane of fascia and may be cleaved on each side into thin planes but the central plane is a thick, powerful, individual, somewhat coarse, fibrous membrane The powerful obturator fascia inferior is cleaved, split, for the transmission of the pubic vessels and nerve The canal formed by the separation is known as Alcock's canal The several membranous planes of some of the fascia in the pelvis endow it with much more utility One plane may tear without the other Several cleavage planes are characteristic of fascia in other localties and are more capable of resisting trauma than a single plane

The coccygeal muscle arises from the spine of the ischium and lesser sacrosciatic ligament, becoming inserted into the side of the coccyx and two lower sacral vertebræ It is a flat musculo-tendinous triangular plane, aiding to close the posterior pelvic outlet Its anterior border is in contact with the posterior border of the levator ani muscle, of which it is practically a continuation backward and covered by the same fascia, viz, the levator ani fascia superior The posterior border bounds the anterior margin of the great sacrosciatic foramen The lesser sacrosciatic ligament which is formed by a degeneration of the superficial muscular fibers of the coccygeus, takes the place of the continuation of the levator ani fascia inferior The coccygeus muscle is fading out of existence, belonging originally to a large tailed animal The origin and insertion of the coccygeus muscle and lesser sacrosciatic ligament are identical They are so strong that practically they never yield so as to be involved in colpoperineorrhaphy However, the coccygeus muscle is described in order to show that its fascia should be named the coccygeal fascia, which can not admit of confusion The inferior surface of the coccygeus muscle is doubly strengthened, not only by the lesser sacrosciatic ligament, but by the superior surface of the great sciatic ligament which represents the proximal tendon of the long head of the bicep femoris The tendon of the long head of the biceps formed an attachment at the tuberosity of the ischium The coccygeus fascia covers the coccygeus muscle and has an area of about 3½ square inches on each side of the median line of the pelvis The pyriformis muscle arises from the lateral portions of the second, third and fourth pieces of the sacrum, from the inferior border of the great sacrosciatic notch and from the great sacrosciatic ligament It passes out of the pelvis through the great sacrosciatic foramen, becoming inserted into the upper border of the great trochanter It is the most posterior muscle which aids in closing the pelvic outlet It serves as a bed on which the sacral nerves may rest It is covered by the pyriformis fascia, which is a continuation of the obturator fascia above and the coccygeus fascia anteriorly After leaving the obturator and coccygeus fascia it rapidly thins out into a transparent thin membrane It is perforated by the internal iliac vessels which leave the pelvis by the great sciatic foramen The pyriformis fascia is attached to the surface of the sacrum internal to the origin of the pyriformis muscle from the posterior border of the coccygeus muscle to the ileo pectineal line which passes along the border of the wing of the sacrum to the sacro iliac joint and finally it is attached to the superior margin of the great sacrosciatic foramen from the ischial spine to the sacro-iliac point The pyriformis fascia covers an area of about five square inches on each side of the pelvis The sacrum is lined by a thin fibrous membrane which we will name the sacral fascia, hence, the internal pelvis is lined by the obturator fascia superior, the levator ani fascia superior, the coccygeal fascia, the pyriformis fascia, and the sacral fascia This nomenclature we recommend as simple, and as facilitating the easy acquisition of the internal fascia of the pelvis

The use of the levator ani fascia superior is *a*, to sustain the pelvic viscera, and is analagous to the fascia tranversalis abdominalis, *b*, to form a pouch on each side for the pelvic viscera, which assists in closing the pelvic outlet above the muscular floor *c*, to fix the pelvic viscera, *d*, with its superior pad of fat and snow-white connective tissue, to support the pelvic peritoneum, *e*, to resist the pressure of the abdominal muscles and the diaphragm, and *f*, to serve the useful purpose of separating the perineal tissue from the peritoneum

This latter anatomic condition limits inflammatory and infective processes from either perineal or peritoneal spaces Further the levator ani fascia superior forms the pelvic floor, and by its strength prevents pelvic hernia The blood vessels are placed superior and the nerves inferior The levator ani fascia superior and inferior limits nearly all fistula in and to one half inch above the anus A disadvantage of the levator ani fascia superior is that it is perforated by nerves and vessels which carry sheaths of connective tissue these sheaths allow infective pro esses to pass from the perineal tissue to the subperitoneal tissue and vice versa Deficiencies occur in the fascia, excavations which are filled with fat The fascia of the pyriform muscles consists of an extension backward of the obturator superior and levator ani fascia superior Both fascial planes blend, the one from the anterior margin of the sacrosciatic foramen and the other from the posterior margin of the cocygeus into a thin membrane which covers the pyriformis muscle and the sacral plexus of nerves The pyriformis fascia is perforated by the gluteal vessels and nerves to gain the gluteal region This plane of fascia is so thin and delicate that one can scarcely dissect it without tearing it The levator ani fascia inferior (anal or ischiorectal fascia) lies in immediate and intimate contact with the inferior surface of the levator ani muscle This fascia begins at the white line and becomes lost on the rectal wall It is very ntimately connected with the muscles The levator ni fascia superior and inferior blend with the rectal allabout one half to three-fourths inch above the anus, d rectal perforations generally occur below the in- tions of the above fascia The fibers of this fascia are included in all deep suturing of extensive colpoperineorrhaphy By including its fibers in the levator ani may be partially restored to the normal relations The sacral and coccygeal fascia lines the anterior surface of the sacrum, it has localized thickenings and thinnings The thickest portions are those located along the lateral margins of the sacrum and especially around the anterior sacral foramina The triangular ligament (deep perineal fascia) closes in the pelvic floor in front It is the result of the union of the obturator fascia extending from both sides toward the center It is a prolongation of the obturator fascia across the pubis, and Winslow called it the ligamentum interossei pubis, Carcassone, the ligamentum perineale, Colles, the ligamentum triangulare urethræ It is the deep blade of the fascia perinei and is an integral part of the obturator fascia It is the middle fascia of the perineum, or Camper's ligament It fills up the deficiency found between the anterior or pubic insertions of the levator ani muscle It is a wonderfully powerful structure in fixing the lower end of the vagina It is stronger in males than in females It is the structure which retains, with powerful grip, the anterior end of the vagina forward and upward The vagina pierces the triangular ligament whose fibers fix themselves in and around the vaginal walls It joins posteriorly with the lower margin of the inferior edge of the superficial perineal fascia If one dissects away all structure from the vagina except the triangular ligament it will become apparent at once what a powerful support it is to the lower e of the vagina The triangular ligament, as its nan implies, is triangular in shape, aponeurotic in structure, extending as a tense septum between the anterio part of the perineum and pelvis It is attached on either side to the rami pubis and ischium Its inferior or posterior inferior margin is ill-defined, blends with the superficial perineal fascia at the ischioperineal fascia, where it gradually loses itself on the lower surface of the levator ani muscle It sustains and fixes the urethral canal It is pierced by the vagina at its base or weakest portion It serves the useful purpose of connecting the bladder and vagina to the pubis, and of retaining adjacent organs in fixed relations By its connection with the ischioperineal ligament (fascia) and levator ani muscle it serves to strengthen the inferior region of the pelvis posteriorly, and aids to fortify the rectum with its muscles By dissection, it is plain to see how the triangular ligament closes the anterior perineal triangle, and the levator ani closes the posterior perineal triangle The triangular ligament extends posteriorly, on each side of the vagina and blends, not only with the lower ledge of the superficial perineal fascia, but very intimately interweaves and blends with the ischioperineal ligaments, making a powerful fixation for the vagina at its lower end The triangular ligament in conjunction with the ischioperineal ligaments lends to the perineal body a "Punctum Mobile"

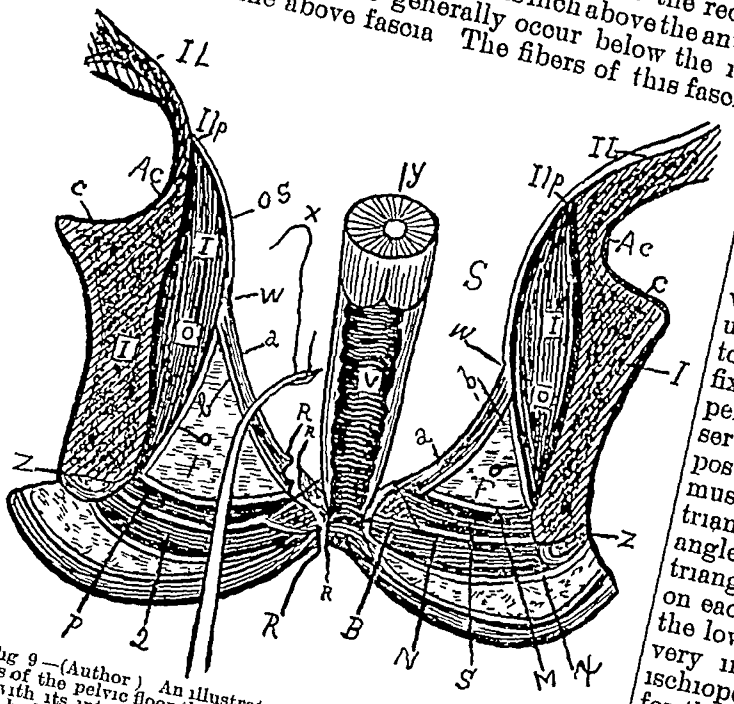


Fig 9—(Author) An illustration to demonstrate that in deep lacerations of the pelvic floor the levator ani fascia superior and inferior is torn with its intervening muscle, the levator ani The rent or tear is shown by R, R, and R, R on the right side The needle armed with the thread (X) will pass through the muscle and its two layers of fascia in order to restore the integrity of the pelvic floor IL, iliac fascia Ilp the beginning of the obturator fascia superior at the ischiopectineal line, OS, the obturator fascia superior W the white line, O the obturator fascia inferior divided by the white line, I O the obturator internus muscle, F, the fat in the ischiorectal fascia, A, the levator ani fascia superior, B, the obturator fascia inferior V, the vagina S intrapelvic space, Y, the cervix, P, deep transverse perineal muscle, and 2 the superficial, B, the sphincter ani externus, M, deep layer of triangular ligament, S, superficial, N, deep layer of superficial perineal fascia

In perineorrhaphy much attention should be given to the factor of including considerable parts of the triangular ligament and the ischioperineal ligaments in the deep suture, which secures a forward curve to the vagina, and also, by forcing medially adjacent tissues, it aids in producing the normal curve of the rectum backward This ligament is a very important structure, serving many purposes of support, and aiding in repair It is continuous with the levator ani fascia inferior, and above it is the levator ani fascia superior The superficial layer of the deep perineal fascia of Colles is a strong fibrous membrane It extends from one ischiopubic ramus to the other This membrane blends posteriorly with the lower margin of the triangular ligament, producing partly ischioperineal ligaments The superficial layer of the deep perineal ligament is less in extent in females than in men, on account of being pierced by the vagina In perineorrhaphy it is of considerable aid in restoring the relation of the parts by allowing the deep sutures to draw the fascia medianward The ischioperineal ligaments extend from the ischial tuberosities to the perineal body They are strong aponeurotic bands of a very resisting character They result from the union of the lower border of the triangular ligament with the deep layer of the superficial fascia The fibers of these ligaments play an important rôle in extensive colpoperineorrhaphy These ligaments form a conspicuous structure in every dissection of the female perineum In the advancing head the ischioperineal ligaments are put on the stretch and gradually forced backward Should they rupture, by extensive flap-splitting and deep suturing the two layers of fascia which blend to make the ligament could be partially restored

Having examined the structure of the pelvis in detail we may now combine the anatomic factors which explain successful colpoperineorrhaphy The first is the restoration of damaged fascia A second important factor is deep suturing A third element in a successful operation is the restoration of function by means of restored muscular relations A fourth is the forcing in the median line of adjacent perineal tissue, and a fifth factor is the flap method of operation whereby there is no denudation or loss of tissue, and the flaps (skin and mucosa) avoid infection and insure primary healing The flap method enables the operator to reach the seat of the lesion, either by splitting tissue or deep suturing with a handled needle with an eye in the end Silk-worm gut which is used in suturing, being non-septic, may remain for weeks in position, like a splint, before removing Among the fasciæ of importance are The levator ani superior and inferior, the triangular ligament and deep layer of the superficial fascia, and the ischio perineal ligament The operation of colpoperineorrhaphy is the result of evolutionary processes of failures and successes In the beginning, it was considered sufficient to unite the superficial or external tissues at the site of the lesion This experiment soon demonstrated its own failure, and later it was deemed essential to restore the deranged and lacerated muscular elements in the pelvic floor The attempt at successful colpoperineorrhaphy by reuniting external tissue at the site of the lesion or restoring deranged or lacerated muscles to normal relations proved a failure to such a degree that it was evident that some other factor played a rôle, this factor was the fascia The restoration of the lacerated tissue at the site of the wound, with the deranged and ruptured muscles, and the restoration of the deranged fascia are the three factors on which successful colpoperineorrhaphy rests To Dr T A Emmet must be given the credit of the view that the pelvic fascia played an important rôle in successful colpoperineorrhaphy Experimental labors on the perineum, in a desultory manner, have been carried on for fifty years But only lately have experimental and anatomic data been judiciously combined so as to render clear what are the useful methods in colpoperineorrhaphy All successful surgical procedures demand an anatomic basis The deranged and lacerated parts in colpoperineorrhaphy must be restored in a manner similar to that in operation for hernia The successful surgical procedures in colpoperineorrhaphy have passed through the same evolutionary process as have the various operations for hernia In hernia we must restore the anatomic relations, the obliquity of the inguinal canal, so that its valve-like action makes it impossible for the viscera to again protrude In colpoperineorrhaphy, not only the anatomic parts should be restored, but the various canals and outlets must also be restored, to ensure permanent success Deep suturing, so essential, is only groping after an anatomic base to restore the ground work The same ideas are involved in the views of discerning surgeons, who suggest that if the sutures include sufficient of the rectovaginal septum, or if they are introduced deep enough to make forward traction, or if they include the sulcus on either side of the bulging vaginal wall, the operation will be successful Dr W R Wilson wrote a short but comprehensive article on the subject, suggesting excellent principles, but modestly claiming that the anatomic basis is still imperfectly understood In the subject of colpoperineorrhaphy the origin of the lesion demanding operation should be studied The cause of the lesion, requiring repair, is almost always the result of (the first) labor, more rarely other forces produce sacropubic hernia The lesions of the perineum may come from the forward movement of the head lacerating the levator ani fascia superior and inferior, with damage to the ischioperineal (ligament) fascia and tearing of the triangular ligament, with consequent inevitable lesion of the deep perineal fascia This will destroy the tone of the posterior vaginal wall, because the fascia has been separated from the vaginal wall near its outlet If the distinct ischioperineal (ligament) fascia be torn, which is quite frequent in labor, the vulvar end of the vagina falls backward and begins its condition of rectocele, its fascial (and doubtless muscular) supports have been torn away With a torn levator ani fascia superior the pelvic viscera will inevitably descend, for it is unphysiologic for a muscle to act as a continuous, tensionized support for viscera But it must be remembered that the fascial layers of the pelvis are not only of value as visceral supports by separate and distinct connection in themselves, but they are of significant importance as serving a means of visceral support and for a point of attachment for muscles lying between their blades The levator ani, which is the most important muscular apparatus on the pelvic floor, serves by its fascial attachments as a visceral support to the rectal and vaginal walls as well as to the pelvic floor, for the uterus is supported by the intact pelvic floor

The pelvic floor may be considered as composed of two widely overlapping valves (Hart) Whatever disturbs the relations of these valves tends toward sacro pubic hernia The anterior pelvic valve is composed of the bladder, urethra, anterior vaginal wall and retro pubic fat The posterior pelvic valve is composed of the posterior vaginal wall, perineum and rectal wall The pubic segment is attached to the symphysis pubis and composed of loose connective tissue The retropubic fat is loose and spongy, the peritoneum may be easily stripped away from the bladder, and the bladder from the vagina In labor, this segment becomes elevated and is the one which easily becomes deranged, or acquires pathologic conditions and especially is liable to prolapse or sacropubic hernia The levator ani fascia superior becomes torn away from the walls of the bladder and vagina, allowing the intra abdominal pressure to force the bladder and vagina downward

When the uterus prolapses (sacro pubic hernia) the anterior vaginal wall appears at the vulva first The strong levator ani fascia has been torn from its walls and when the same fascia has been extensively torn from the bladder it prolapses also In vesical prolapse the peritoneum with its many cleavable planes of subperitoneal (fascia) tissue becomes torn from the bladder The sacral valve of the pelvic floor, consisting of the posterior vaginal wall, the perineum and rectum, is attached by strong fascial connections interwoven by muscles to the coccyx and sacrum In labor, this segment is forced backward and straightened out If it becomes defective by laceration at the perineal body the vagina loses its normal curve and sacro-pubic hernia is initiated, i e, retroversion begins, which is the inevitable factor in sacropubic hernia The uterus itself has nothing to do with prolapses Intra-abdominal pressure and defective sacral and pubic segments account for prolapse, the sacral segment is fixed, the pubic segment is movable

The functions required of the pelvic floor are to resist intra abdominal pressure and to allow rectal and vesical functions The structural anatomy of the pelvic floor must not only be studied in general as to it segments, valves, muscles and fascia but each individual organ should be studied as regards its supports The uterus has its individual supports, which, though not separate from the fascia and muscles, should be well considered, for colpoperineorrhaphy may be required for (prolapse) sacro-pubic hernia without visible lacerations The first elemental individual supports of the uterus are the uterorectal (sacral) ligaments They consist of two folds of peritoneum embracing muscular and connective tissue extending from the posterior surface of the cervix to the rectum (perhaps some fibers do extend to the sacral fascia) These ligaments are an extension of the muscular connective tissue fibers of the upper end of the vagina backward As Dr Frank Foster notes, the vagina and uterorectal ligaments form a balance beam on which the uterus rests Yet it should be borne in mind that organs do not rest on bases, but are swung on supports or mesenteries The brain, liver, heart and uterus are all suspended by supports and do not rest on other organs or bases The uterorectal ligaments are powerful, peritoneal, muscular and connective bands which vigorously suspend the uterus by the neck Careful dissections and vaginal hysterectomy will demonstrate that the uterus could not descend without the uterorectal ligaments became elongated

These ligaments are a part of the musculo-fascial support of the pelvic viscera The vaginal tube supports the uterus by being well embraced by the levator ani fascia superior and the levator ani muscle, and also by being well padded and surrounded by fascial planes of connective tissue fixed in its walls and adjacent structures Fat pads and acts as a support by stiffening folds

In colpoperineorrhaphy, it is well to remember that we have a fixed pelvic segment and a movable or displaceable segment It will aid in repair The movable pelvic segment comprises the urethra, bladder and vaginal walls This segment is bound together by peritoneum on a very mobile base and by a considerable mass of loose connective tissue

This segment becomes displaced by labor, distended bladder, vagina or rectum If its fascial connections become torn, sacropubic hernia is inevitable The fascial connections are considerable above the vulva, consisting of the levator ani fasciæ superior and inferior and to some extent of the levator ani muscle Sacropubic hernia, arising from lacerated fascia of the movable pelvic segment is recognized by the vagina and bladder bulging downward at the vulva and making the vulva appear as a waist with the puckering string gone The worst and most damaging cases of laceration are those which begin from the inside and progress outward, i e, the fascia begins to tear high up in the rectovaginal septum, on the sides of the bladder and vagina These are the cases which present distressing symptoms, when standing are worse on account of disturbed circulation and are pronounced "prolapse" by the general physician In such cases the anterior vaginal wall appears first at the vulva, then the cervix and finally the posterior vaginal wall The bladder gradually sags downward and difficult urination is added to the already existing train of symptoms In lacerations of the sacral segment of the pelvis the lesions are more visible The perineal body suffers especially It straightens out the fixed sacral segment and retroversion and inevitable subsequent sacropubic hernia results The visible laceration of the perineal body was originally considered the chief requisite for repair and also the type of colpoperineorrhaphy But the study of the pelvic fascia shows why the operation failed or succeeded Frequently it may be observed that the perineal body is visibly torn, but no evil consequences follow, because the fascia remains intact The rectum belongs to the fixed segment It does not prolapse, but its wall stretches, elongates As the advancing head forces forward and tears the levator ani fascia superior and inferior as well as the ischioperineal ligaments, the levator ani muscle also becomes deranged but practically the restoration of the fascia restores the muscles The muscular layers of the pelvic floor are two—superficial and deep connected—and blended at the perineal body both by the muscular and fascial relations The deeper layer is the levator ani muscle which descends from the sides of the pelvis in the form of a boat or bowl to its attachments on the pelvic floor The superficial layer consists of the transverse muscles of the perineum, which extend from the tuberosities to the center of the perineum and also the bulbo-cavernosus, which surrounds the vaginal outlet All the muscles are related to fascia, as the levator ani inclosed in double blades of fascia, i e, the levator ani fascia superior and inferior The deep transverse muscles lie between the triangular ligament and Colles fascia The bulbo-cavernosus and superficial transverse muscle lie between the two superficial perineal fasciæ The ischioperineal fascia is but the thickening of the lower border of the triangular ligament and Colles fascia The significant importance of the fascia of the pelvis becomes at once apparent, not only in maintaining the integrity of the pelvic floor, but in all repair of the same The pelvic fascia is the chief element in maintaining perineal muscular relations The pelvic fascia may be divided into deep and superficial layers, according to the deep and superficial layers of muscles The deep pelvic fascial layers are united to the more superficial pelvic fascial layers in the perineal raphe, holding the pelvic fascia as a unit The superficial fascial layers of the pelvis are attached from the ischial tuberosities to the pubic rami and stretch across the anterior perineal triangle They shut off the pelvic outlet except at the vulvar orifice Fascia may be torn without its associated muscle being torn In perineal laceration the muscles lying between the fascial layers may become separated as to loops or as to the attachments of one or both ends Also the fascia ani muscle may be lacerated in different localities and this allows complete repair

When the muscular layer between the fascial layers separates, the muscular fibers retract irregularly toward the proximal end, leaving gaps which are difficult to effectually repair The rupture and retraction of the levator ani with its fascia makes the deep sulcus found on each side of the bulging rectocele, because the fibers of the levator ani retract laterally toward the pelvic walls It is evident there is a deeper factor in perineal lesions than visible lacerations The deficiency in perineal lesions is not in proportion to the apparent extent of the injury Every physician has noticed multipara with considerable external laceration of the perineum, with apparently little discomfort, and with the pelvic organs but slightly disturbed, while in other cases, with slight apparent lesions, complaints are serious I have seen extensive visible lacerations with almost no complaints and apparent health Again, we may observe cases when the perineum does not appear lacerated, but the prolapsed vagina, the bulging rectocele and vesicocele appear at the vulva in a remarkable degree In fact, as Dr Emmet remarks, it looks like a bag which has lost its puckering string There is a different explanation for each of the above classes In one, the pelvic fascia has suffered in the lesion and in the other, only a few muscle loops and possibly the perineal body When the lesion involves the pelvic fascia its consequent result is that the circulation is deranged seriously, because the vessels are held in definite relations by the fascial planes, hence the discomfort on standing and exercising is from congestion Baker Brown simply united the torn tissue at the vaginal outlet Seldom does this simple measure afford any real relief from perineal laceration, for subjects with such visible slight traces suffer but little In general the operations for the relief of perineal laceration are a failure If the rectovaginal septum (fascia and muscle) be not brought in the grasp of the deep sutures success will not be obtained even though the vulva be closed The secret of Emmet's success lay in the denuding of the vaginal septum, i e utilizing the tissue posterior to the vaginal wall In fact, if the levator ani fascia superior and inferior be not lacerated the subject suffers but little from the lesion, though the perineal body be torn through to the rectum The levator ani fascia superior forming the gutter or sulcus on each side of the vagina is firmly blended with the vaginal canal as the same strong fascia in the male surrounds the prostate In labor, in perineal laceration we should not merely look for lesions in the posterior commissura of the vulva, for that is done by the escaping head and shoulders, and is visible, but we should look for concealed lesions of the strong fascia, the sulcus on each side of the vagina The most serious lesion of labor may occur without visible external injury This lesion is in general a separation of the fascia from the vaginal wall If the fascia be torn from this, the posterior vaginal wall will not be drawn against the anterior and the canal will be filled within it will be like an open collapsed bag The fascia together with the muscles holds the vaginal and rectal canals in a closed condition, excluding air The ballooning out of the vagina with but little injury to the perineal body is indicative of fascial lesions within the pelvic cavity along the vaginal canal The vaginal rectocele is due to the drawing aside of the levator ani fascia superior and but little to the external laceration The beginning of discomfort on assuming exercise is due to deranged pelvic circulation, to dilation and straightening out of veins to non-uniform support of the blood vessels and nerves by the proper connective tissue The advancing head crowds the fascia forward, and if the labor is terminated without forceps, the rents begin chiefly in the rectovaginal septum It is well to decide what and where the laceration is, so that tissues may not be either denuded or split unnecessarily, for it is not unfrequent to see tissues united which were never involved in the lesion Perhaps sufficient has been demonstrated, anatomically and clinically, to show that the lesions of the perineum which disable and discomfort the patient are chiefly lacerations of the fascia and secondarily of the muscles On this view we base our labors If this be the case, we can easily see that Emmet secured success by denuding an elliptical area of the vaginal mucosa on each side in the vaginal sulci The curve of the denuded area corresponds to the posterior curve of the rectovaginal septum, and is situated within the introitus Now, by introducing deep antero-posterior sutures, the levator ani fascia superior and inferior may be reunited, restoring the curve of the posterior vaginal wall and the fascial layers at the vulvar outlet In reuniting the levator ani fascia superior and inferior the levator ani muscle becomes also reunited, but in an imperfect degree The levator ani is closely embraced by its superior and inferior fascial planes, as from its origin, insertion and relation it depends on its closely associated fascia The restoration of the function of the levator ani muscle must be accomplished through restoration of its intimate planes of fascia If success depended on the muscle chiefly, it would be necessary in rectocele to reunite the separated levator ani loops anterior to the rectocele in the median line or raphe, so the symmetrical muscular action would be restored It is true that to secure muscular action of the levator the loop must be so repaired that the fibers shall start to act approximately from the raphe on both sides, but this is accomplished by reuniting the levator ani fascia as near as possible in the median line, which brings the muscular loops with it The levator ani fascia superior and inferior is really a sheath for the levator ani muscle to accomplish its functions The sheath can not be torn without creating damage to the muscle In rectocele, this fascia is so torn and stretched that the anterior wall of the rectum loses its muscular support and bulges forward Whether the sutures be introduced antero posteriorly or transversely, it matters but little, if they include in their grasp the levator ani fascia existing in the lateral sulci of the vagina, and whatever is done to be successful, the rectovaginal septum, composed chiefly of fascia, must be restored to reproduce the normal curve of the posterior wall of the vagina Mr Lawson Taits' flap operation on the perineum accomplishes exactly what Emmet's operation in the lateral vaginal sulci does, with the exception of denudation Both operations, when properly and successfully executed result in the restoration of the continuity of the deep and superficial fascial layers of the pelvic floor, with the establishment of partial or complete muscular function The deep sutures reunite the structures (fascia and muscles) at or near their normal points of attachment Anatomically then the object to be obtained in an operation for colpoperineorrhaphy are

1, the restoration of the levator ani fascia, superior and inferior, 2, the reunion of the fibers of the levator ani muscle so that it will functionate—both fascia and muscle must have relations at the perineal attachment, 3, the restoration of the transverse perinei muscles which draw the vagina lateralward, causing it to remain open 4, the restoration of the ischioperineal ligaments in regard to the perineal body, 5, the posterior curve of the vagina must be reproduced by restoring the rectovaginal septum, 6, a new perineal body should be restored so that the natural backward curve of the rectum and forward curve of the vagina should persist, i e, normal relations should be established between the perineal center or body, on the one hand, and fascia and muscle on the other The perineal body—"punctum fixum"—of vulvar surface relations should be restored

The pelvic floor is composed of muscles, fasciæ, areolar and elastic tissue These structures are interwoven into distinct though complicated relations and fill the gap of the pelvic outlet The pelvic floor is composed of two halves, whose structures arise from the lateral walls and join in the medium line There are two muscles, two fasciæ and two ligaments of each kind If one will carefully study in dissection the levator ani and the bulbo-cavernosus muscle he will be impressed with their functional comparison Both are sphincter muscles Both have connection with skin as most true sphincter muscles possess The three points of insertion of the bulbo cavernosus may be considered as one muscle They contract together and have a similar function The common feature of the two muscles is their attachment to the terminal fibers of the rectum and vagina The sphincter ani is closely united to the muscles of the pelvic floor by tendons and fascial attachments The object of the muscles of the pelvic floor is to control the lower ends of the vagina and rectum Fascial structures are common to muscles which have to afford sustaining power, as those of the abdomen, back and thigh

(To be continued)

A STORY OF CHICKAMAUGA

BY R STANSBURY SUTTON

Major and Chief Surgeon U S V, Commanding Second Division, First Army Corps Hospital

My apology for intruding upon the columns of the JOURNAL is multiple I am a veteran of the Civil War, and I did duty upon the battle field of Chickamauga, upon which I have been again on duty since the 7th day of July My knowledge of hospitals is of long duration, and extends to the hospitals of Europe as well as those of our own country Moreover, while the hospital under my command needs no defense for its efficiency under my own administration, I feel that my colleagues in the army and in other hospitals have been most unrighteously abused—from the Surgeon-General at Washington to the humblest lieutenant serving as an assistant-surgeon in the regiments In this defense of a noble profession, I do not excuse dereliction of duty or stupidity in any medical officer Occasionally a medical officer is found who is incompetent, not always because of want of medical knowledge, but by reason of his disposition, which disqualifies him for his position Such men are in the army, but they are few

Let me photograph for you the pictures in my mind as they were registered On July 6th I reached Chattanooga at 8 30 P M My hotel for the night was the Read House At 5 A M of the 7th I arose, put my head out of the window and counted twelve soldiers lying drunk in the street At the Central Depot, a few hours later, waiting for a train to Lytle, where I must report for duty, I observed soldiers drunk and in the company of prostitutes A police officer at the depot, of whom I made many inquiries suggested by my knowledge of Chattanooga at the time of the Civil War, told me that the town was full of drunken soldiers and prostitutes, the latter numbering many hundreds, of all shades of color and damnation

A railroad ride of an hour, between Missionary Ridge and Lookout Mountain, southward, and the station of "Lytle" or "Battlefield" was reached Wooden sheds surrounded a space opposite the depot, forming an aggregation of restaurants, fruit and nut vendors, variety shows and houses of prostitution An hour later I reported for duty and was assigned to the staff of Brigadier-General Rosser, of Confederate army fame

In the afternoon I returned to Chattanooga and slept that night in the Southern Hotel, at 8 30 next morning I counted, from the window of my room, seventeen soldiers lying drunk in the street Hundreds of others lay about the town in the same condition Who was responsible for this? I ask the honest reader if the sickness in the army springing from drunkenness and prostitution was due to the carelessness of the medical staff of the army? This loose military and civil government had been prevailing for weeks, and the army was suffering from dissipation and prostitution Not less than 5 per cent of about 50,000 men were incapacitated for their full duties by syphilis or gonorrhea or both They flocked in at the sick calls, the quarters were besprinkled with them, and they furnished fully 80 per cent of the surgical patients of the field hospitals How did they conduct themselves there? Their appetites were not inspired, they craved full diet, and, because they were in the hospital, wanted all the delicacies provided for sick men who could eat but little and drink soup and milk They resented their grievances by writing letters to newspapers abusing the hospitals and the doctors An anxious mother from the far North becoming alarmed, came down to Chickamauga She had read these letters Her own son had written her his views and told her of the horrors of the army hospital Upon her arrival she poured out her seven vials upon the hospital and the staff, and then demanded that she be conducted to her "darling boy" The surgeon addressed, by this time a little warm under the collar, said "Your son is out in the woods under the trees, he is doing very well, but he has had a very bad attack of gonorrhea" "What's that," she snapped out "Clap, madam, if you please" Many examples of the outrageous behavior of this class of patients might be given But the subject will not bear investigation in the daily press, notwithstanding its libelous and criminal attacks upon the hospitals and their medical staffs Can you accuse the doctors for not preventing this? You can not do it The civil authorities of Chattanooga, to their eternal disgrace, are largely responsible for this matter They bowed down before the brazen image of cupidity and resolved to do nothing that would stay the draft upon a soldier's pocket in their morally rotten corporation

On July 8 I took the position of Brigade Surgeon on General Rosser's staff I remained on this staff as Brigade Surgeon until August 1 General Rosser is a man who has been educated in the art of war from West Point through all the wars of the last and present generation He is kind and resolute, companionable and pure in his daily conduct, indefatigable in the pursuit of his duties despite poor health Not a drop of spirituous liquors of any kind were ever seen at his headquarters, and as we stood about our mess table, with its plain and simple food, frequently in the rain without cover, General Rosser, with all heads uncovered, never failed to invoke the blessing of God upon the table and its participants But General Rosser, like all old generals of the army, was physically impaired Their livers are bad, their digestive organs generally are permanently deranged, and the dynamo in every one of them has begun to fail General Rosser broke down and returned to his home in Virginia, and General Poland, Division Commander, died Other old generals, whom I saw, had seen their best days, and altogether would have formed a magnificent advisory board, but their places in the field should have been filled by younger men Surely the medical profession of the army were not responsible for this

Within a week after I joined General Rosser's staff, I was struck with the difference in the morning sick reports of the different regiments forming the brigade It stood in the relation of 1, 2, 3 Why was the First Pennsylvania regiment first, the Fourteenth Minnesota second and the Second Ohio third, or 10, 20, 30 sick? The camp was the finest I had ever seen, the food was good and abundant The weather was then fine later it became atrocious The Pennsylvania regiment was an old National Guard regiment, their officers and men were city-bred, and before entering the service they had culled out of the regiment every man and officer of doubtful health They slept in the company streets, when they were dry, and kept their camp like a pin The Fourteenth Minnesota physically were apparently in advance of the Pennsylvania regiment, but they were largely country-bred, slept in their tents, three and four to the tent The tents were not ventilated by window slots at either end of the ridge pole, and they usually dropped the flies at the entrance The Second Ohio stood below both in health record A hollow in the land stretched through the camp The First Pennsylvania and Fourteenth Minnesota were at its head, the Second Ohio at the foot Later they got the wash from the rains, and in spite of magnificent efforts, like the other two regiments, concluded to move This brigade, officers and men, numbered about 3600, with but one medical officer to a regiment The colonels, Good, Van Duzee and Kertz, were able men, ever vigilant, kind and devoted to their duties, and I consider it a great privilege and honor to add them to the list of my many army friends

A regiment of troops in the field are too much for a single medical officer Each regiment was originally provided with three, but two out of each regiment were detailed to other duties At the field hospital these detailed surgeons were busy, hard-working men But many of them were detailed to the ambulance corps, where they did nothing but play poker, crack jokes and watch the mules switch off flies, or sometimes do other amusing things such as mules will do I sent a remonstrance through military channels to corps headquarters, setting forth my complaint and asked that the medical officers of the brigade at the ambulance station be sent back to their regiments Lieutenant Colonel Huidekoper, the corps surgeon refused to return my medical officers The division surgeon interfered and got one of them back—Lieutenant Dorsey of the Fourteenth Minnesota

I will digress here to speak of the physical character of the soldiers of the entire Division—13,000 men Serving as a member of the Discharge Board, I was almost daily examining soldiers for discharge from the army Among these men I found no end of hernias, many of them existing at time of enlistment One man had inguinal hernia and club-foot Many had severe astigmatism Some were deaf, scores of them had constitutional syphilis, and many had tuberculosis A great many had organic disease of the heart, and a host had bad feet or bad teeth How could a lot of physically bad men fail to make a large sick list? Were the doctors responsible for this? The medical men who passed these men into the service certainly were, but they got only forty cents per capita for examining these men as recruits They had an excuse for poor work It was the same as that attributed to Mark Twain when a pilot on the Mississippi River, when he was upbraided by the captain, to whom he replied that he thought he was "pilotin" very well for $12 a month

On August 1 I was detached by higher authority and put in command of the Second Division, First Army Corps Field Hospital of 263 beds At the hospital I found 162 patients, six medical officers, a lieutenant, a commissary of subsistence, and 39 out of 96 men who should have composed the hospital corps Out of these 39, I was to find kitchen men, laborers, guards, clerks and nurses Of the number on hand some were physically ill suited or actually ill Six noble doctors were on duty—Majors Charlton, Bagerly and Myers, Captain Dutton, Lieutenants Little and Nesbit—taking all the three watches of eight hours each, and 162 patients I was cut down to depend upon twelve or fourteen nurses for day and night duty These were soldiers with only accidental experience, and but little of that, in civil life Seventeen sick soldiers lay upon the ground There was poor preparation of food, a limited supply of proper food for the very sick Major Charlton, whom I relieved, was ill The fault in this instance was twofold The division surgeon and the purveyors of lumber, cots, etc, were to blame I soon, but after much perplexity, got over the difficulties and the hospital flourished Typhoid fever, next to venereal disease, has been the scourge of the army at Camp George H Thomas What was its origin? Why its prevalence?

Let us take a side view of the subject The typhoid bacillus is a specific germ If introduced into the intestines of man it produces a train of symptoms known as typhoid fever Now, was it in the water or was it in the food? Suppose for a moment that it was not in either the water-supply or army rations How did it reach the soldiers? It is a fact that typhoid fever was prevailing in the neighborhood of Chickamauga Park before the army camped there It is also stated that it developed in the first regiments who camped in the park The people in the neighborhood sold milk and farm products to the soldiers and if they had typhoid fever as it is known they had they likely conveyed the typhoid germs in their milk cans and probably in their fruit They watered their milk probably with infected well water, and handled their sick and their fruit. Typhoid fever was not epidemic at Camp Thomas, and its spread was not rapid until within two weeks. It was spread from detached foci of infection and not from one focus. I am convinced, after no little investigation, that the water-supply from natural springs and the pipe-line at Chickamauga was good and did not contain the typhoid germ. It was not in the army rations. I believe that it was first introduced by the hucksters, that troops arriving brought soldiers infected at home or in other camps, and that it spread from one to another in other ways than through the pipe-line or commissary department. But were the doctors responsible for its introduction? Not at all. Were they responsible for its expansion? They fought it as well, probably, as they could in army life and under the difficulties attending camp practice. In the hospital which I had the honor to command, out of more than 900 patients we had 14 deaths from all causes, probably 8 from typhoid fever. The mortality in the Second Division, 1st Army Corps, was certainly not excessive.

The Red Cross Society, the National Relief Association and the United States Government provided more than enough. The combination was lavish. Some things I would have liked to have had more of. Wine, brandy and whisky were shortages, but of everything else to eat and to wear in a sick-bed, I had an abundance. On the 26th of August, I turned over a surplus of nearly half a ton of materials to the Red Cross Society. My work was done at Camp Thomas, and the day following we moved to Knoxville. As I left Camp Thomas, I received a check from the Red Cross Society at Pittsburg, Pa., for $500.

The hospitals and camps have been full of blooming liars, who have filled the newspapers with the most alarming stories of cruelty and neglect. And for the sake of justice they must be met and denied. Cots and lumber were hard to get about August 10, but we soon broke the blockade and got all we needed.

At Camp Thomas or Chickamauga Park the Sternberg Hospital is now open. It is designed with the expectancy of reaching 1000 beds. It is a field hospital. The quarters are the army hospital tents and wooden barracks. The beds are iron, mattresses hair, mosquito canopies over all, and trained female nurses are in attendance. The world has never seen such a field hospital. Hundreds of soldiers will there find more luxury than they ever knew at home, yet the day when the public press will put the Sternberg Hospital in the crucible will likely arrive.

Let the noble fathers and mothers of this Nation know that the medical profession have been as devoted to their sons on the historic field of Chickamauga in this war as were our colleagues to the Nation's sons during the Civil War. It has been God's mercy in prolonging my good health and love of country and giving me the ability to say that I witnessed the devotion to duty of the surgeons in the Civil War and in this war upon the same field of Chickamauga. The soldiers of this war have had their trials, but I can call upon my comrades of the Civil War who are out again now to say whether the following assertion is true or not. The soldiers, sick and well, at Chickamauga Park, have had a picnic as compared with the soldiers there in 1863 and 1864.

The park is infected now and will be rapidly abandoned, as it should be. The sink problem has been mentioned by the newspapers. It is a very difficult one to discuss. The problem in ordinary soil, with plenty of help and good tools, is easy enough. But in Chickamauga Park conditions of soil prevail which make it very difficult to construct a sink with ordinary labor and tools. The soil is tough clay deposited in a bed of rocks of all shapes and sizes. The clay stratum is deep. It is possessed of poor absorbing qualities, and if the rain fills the sink with water it holds it like a barrel. To get a sink a few feet deep is of little consequence. It is necessary that the depth of the sink be 12 feet, and for working space, it is therefore necessary that they be 5 feet in width and 12 feet long. Such a sink requires many reliefs of labor. After completion it must be surface-ditched, when to this you add the ditching of nearly three acres of ground for a hospital site, one may gain some idea of soldiering.

To the regimental commanders of the Second Division, First Army Corps, I return many thanks for the large details of men to aid me in putting the grounds of the hospital in good hygienic condition. When I left the hospital site on the morning of the 27th of August, the entire plant having been delivered for shipment at Rossville, the grounds were ready for a picnic, not a shred of anything being left unburned, not a sink being left otherwise than in a perfect state of innocuousness, all being filled, and banked with lime and earth. If your readers have had some of the deceptions removed from their minds and will kindly turn their wrath from the medical officers of the army, I will be well repaid for the time spent upon this communication.

THE RETURNING ARMY

BY N. SENN, LIEUT.-COL. U.S.V.

CHIEF OF THE OPERATING STAFF WITH THE ARMY IN THE FIELD

The war is over and the heroes who freed the Western Continent from Spanish despotism are returning home. The first war of invasion on our part has been a short, decisive one. Only four months have passed since the Chief Executive issued the first call to arms, and more than we expected has been accomplished. The outside world, which has sneered too long at our fighting strength as a nation, has been convinced that it is dangerous to trifle with Americans in matters of war. In less than two months after war was declared we had more than two hundred thousand men in the field, eager and anxious to face the dangers of active warfare. Less than one-half of this army took part in the invasion. The enemy's navy was entirely destroyed, not a single ship that came within range of our guns escaped. The proud Spanish fleet is a total wreck in American waters, a source of pride to our navy and a significant object lesson for all foreign nations. Santiago fell before our victorious army, Porto Rico yielded after a few skirmishes and Spain accepted our terms of peace without much argumentation, after the hopelessness of her cause had been demonstrated by our invincible army and navy. Peace has been restored, and the returning soldiers of the volunteer army will soon return to citizenship and resume their ordinary vocations of peaceful life.

What a contrast between the invading and returning army! This contrast has reference not only to size but also to appearance. Thousands have died from wounds and disease. Yellow fever, dysentery, malaria and typhoid fever have been and continue to be our most formidable enemies. We had no great difficulty in silencing the Spanish guns, but we have been less effective in preventing the origin and spread of these, the greatest terrors of camp life We can calculate with some degree of precision the loss of life sustained in battle, but it is impossible today to estimate the ultimate damage inflicted by disease The naval forces scored the greatest victories with little loss of life, they escaped disease and its consequences, to a large extent, and were subject to little or no privations The invading armies suffered the brunt of privation and discomforts incident to an active campaign The troops in camps who were denied the privilege of taking part in the invasion of Cuba and Porto Rico had their share of deaths, sickness and hardship It is safe to say that not half of the soldiers engaged in this short war are in a fighting or working condition on their return home It is a sad sight, indeed, to witness the disembarkment of a transport arriving from Cuba or Porto Rico Every one of the vessels brings from fifty to one hundred and fifty disabled men requiring medical treatment All of the men left on the outgoing transports in good health and cheerful mood, all who arrive show the effects of the campaign Many have died in our new possessions, many have been consigned to the sea on their way home, others have reached the shore in a dying condition The crowded transports, the inadequate provisions for proper food, have made the voyages to and from the seat of war a source of hardship instead of health and pleasure The emaciated forms, the sunken eye, the hollow cheek, the pale, bronzed faces, the staggering gait, show only too plainly what can be done by disease, a tropic climate and improper food in disabling an army in a few weeks In this respect our experience is a repetition of that of our enemy It is well known that the Spanish army lost 50 per cent of its fighting force from the same cause in two months after landing in Cuba The Spanish surgeon I met inside of the lines of the enemy, four days before the surrender of Santiago, when we delivered to him, under a flag of truce, sixteen wounded Spanish soldiers, informed me that when his part of the army reached Cuba the men were all in good health, and that now many were sick and none well He drew a sad picture of how their ranks were thinned out by yellow fever, malaria and dysentery The outbreak and spread of typhoid fever in our home camps, so early during the campaign, is responsible for more deaths and suffering than any other cause Many of our soldiers carried the infection with them to Cuba and Porto Rico, and were taken ill on the transports or soon after landing It is much more difficult to keep typhoid fever out of the army than yellow fever The yellow fever which our troops in Cuba encountered was of a mild type Comparatively few died and most of the cases recovered after an illness of but a few days Typhoid fever runs its typic course of three weeks or more, little influenced, as far as time is concerned by medication It is a disease which, above all others requires careful nursing The necessary attention to typhoid-fever patients in nursing and treatment is a matter difficult to obtain, even in a well equipped hospital with all needful appliances The management of such cases in field hospitals is necessarily attended by many difficulties which tax to the utmost the experience of the medical staff and nursing corps Considering the limited resources at our command in the treatment of this disease, in our home camps and our new possessions, it is surprising that the mortality has not been greater The Sisters of Charity and the trained female nurses from different cities, have done most satisfactory work in our home camps, crowded with typhoid fever patients Many a soldier on his recovery from the disease will feel grateful for their faithful services

CAMP WIKOFF

Camp Wikoff is now a great hospital It is located on Montauk Point, L I, a narrow strip of land surrounded on both sides by salt water The country is hilly and treeless and the sandy soil is covered with a scanty growth of grass Between the hills are cup-shaped depressions with a marshy soil, which after rains are filled with stagnant water These diminutive marshes threaten danger in case of a prolonged encampment They are undoubtedly, all of them, the natural breeding-places of the plasmodium malariæ They will soon become contaminated with the fecal discharge from hundreds of typhoid fever cases, as many of the sinks drain directly into them I am told that the water-supply from the artesian wells, while not ample, is otherwise satisfactory The small railroad which terminates here from New York, monopolizes the whole business of transportation, as this exclusive right was made conditional in securing the ground for camp purposes This is greatly to be regretted, as steamer communication could be readily established, which would facilitate the present unusually large passenger and freight business between the camp and New York Politics and personal interests have figured conspicuously in the management of the present war Departments have been severely criticised, when a thorough investigation would often reveal a power behind the throne If we had steamer traffic between here and New York we would not have to wait for days for the so much needed supplies The little railroad has had sufficient influence in cutting off competition and in increasing correspondingly the value of its stock, and we here are suffering the consequences of this Judas Iscariot bargain The whole little peninsula is a tented field Regiment after regiment is arriving, day after day seriously testing the quartermaster's department All the troops that came from Cuba must land here to comply with the quarantine regulations A detention hospital has been established near the landing, to which all suspects are consigned for the required length of time Near the hospital a large disinfecting plant has been erected So far no cases of yellow fever have been imported The general hospital contains at the present time (August 26) nearly one thousand patients and all the sick in the camp will swell the number to 1500 The landing of so many sick in such a short time has brought about an overcrowding which, with the present facilities and resources could not have been prevented Colonel Forwood, Assistant Surgeon General, selected the camp site, and was the first man on the ground His immense military experience gained during the War of the Rebellion, fitted him in an admirable way for the difficult task imposed upon him Colonel Forwood is an authority in military surgery and endowed with excellent administrative talents His work here will be the crowning effort of his life He has worked night and day since he has assumed his duties here He is a friend of the soldier and will not leave a stone unturned to be of service to him He has exclusive charge of the hospital construction and his work was much admired by two staff surgeons of the German army, Drs Steinbach and Wildemann, and by Lieutenant-Commander Tomatsuri of the Japanese navy, who came from New York to the camp with me As they expressed themselves, the field hospitals here were the best they had ever seen Colonel Forwood is ably assisted in his arduous duties by Majors Heitzmann, Brown, Nancrede and Wing and a large staff of acting assistant-surgeons The writer, on his arrival, was placed in charge of the surgical work An operating tent was erected and placed in working order with the assistance of two Sisters of Charity and Acting Assistant-Surgeon Greenleaf The tent is floored and divided into four sections The front part is the operating-room, with two side tables two feet in width the whole length of the room The tables are covered with rubber cloth An army operating-table and a few stands constitute the balance of the furnishing of the room The next section is open on the sides to allow a free current of air and serves as an office The next compartment is the preparation-room, fitted out with formaldehyde and steam sterilizers and sufficient shelf accommodations The last section is used as a storeroom for dressings, splints, antiseptics and drugs necessary for the treatment of surgical cases

Gen Joseph Wheeler is in command of the camp, and although debilitated by the campaign and disease, he attends to his duties with a regularity and devotion which have characterized his whole military career The sick are being cared for at the present time by fifty Sisters of Charity and sixty trained female nurses One of the things that was greatly admired by the foreign military surgeons was the efficient work of the hospital corps They were charmed with the way in which the patients were handled and the gentlemanly conduct of the litter-bearers Less praise was bestowed on the military bearing of the men in camp, from the highest officers to the ordinary private The military spirit seems to have been fully subdued in the enemy's country The sentries move about sluggishly and seldom deem it worth while to come to a "present arms," no matter who may come within saluting distance Men walk about in clothes showing only too distinctly the absence of whisk-broom or brush since they left Cuba Guns, bayonets and scabbards have become rusty and show an entire lack of proper care All drills are suspended and the whole camp presents more the appearance of a picnic ground than a military post Officers and men are evidently impressed with the idea that their work is done, and while away their time in a way requiring the least amount of energy and exertion possible In this respect our troops form a strong contrast with the German army when it entered Paris, after one of the most bloody wars and after a prolonged siege full of hardship and privations On that occasion every soldier was in a condition to go on parade and to pass with credit the inspection of the most exacting officer Such looseness of discipline as seen here at this time is not calculated to inspire the outgoing army with the proper military spirit that should be maintained and cultivated under the most adverse circumstances Strict military bearing is also sadly lacking among the medical officers—a source of disappointment and surprise to the corps of acting assistant surgeons, who entered the service with the full expectation that the reverse would be the case

Camp Wikoff, Montauk, N Y, Aug 27, 1898

THE NATIONAL CRY

BY N SENN, LIEUT COL U S V

CHIEF OF THE OPERATING STAFF WITH THE ARMY IN THE FIELD

Unrest, criticism and grumbling are the accompaniments and heritage of every war These symptoms of war fever have been unusually well developed during the war just ended, and they will be discussed for a long time after the treaty of peace has been signed After an uninterrupted reign of peace for more than thirty years, the war cloud that came upon us so suddenly and unexpectedly provoked a commotion among the people unparalleled in degree and extent since the War of the Rebellion All eyes were turned in the direction of the seat of war, and the contents of our enterprising and prolific newspapers were devoured with an eagerness unknown in any other country It is strange that with all this great national unrest the current of commerce and business pursued its natural course While our troops were engaged in war in foreign lands, the tilling of the soil the hum of industry and the ordinary avocations of life continued as though harmony and peace reigned universal The American never forgets that patriotism is not limited to the battlefield The conscientious performance of duties at home, the fireside, the farms, the workshops, the manufacturing and business places is one of the things essential in the successful prosecution of a war This fact was recognized by our people, and the result has been that the prosperity of our country has suffered little, if any, during our first war of invasion Criticism is a part of human nature It is seen everywhere It affects the educated as well as the ignorant, it extends from the cradle to the grave, it involves one sex as much as the other, it moves the well as much as the sick, it infects the pulpit as well as the stage, and it comes to the surface in the army from the commanding general down to the lowest of all privates It is amusing to listen at a camp fire to the remarks made from all sources as to how the campaign should be conducted The average private discusses the most complicated strategic problems with an ease as though he were repeating the multiplication table or the Lord's prayer The generals high in command ease their conscience by criticising their subordinates most unmercifully, if any thing has gone wrong Wise as well as ignorant men, a thousand miles away from the seat of war, have their convictions as to what should be done and are free to express them Criticism increases in severity and extent in proportion as confidence is weakened and undermined As we live in a free country criticism finds a fertile and productive soil everywhere and anywhere The unbridled liberty of the press encourages and fosters it Like swearing and other vices it is engendered by environments Just and wrathful criticism is legitimate, criticism the outpouring of impure selfish motives is baneful Our energetic, enthusiastic press is entitled to a great deal of credit in giving to the public the war news so promptly and completely, often at an enormous expense and severe danger to life The American reporter has no equal in any country for obtaining news regardless of cost and risk The reporters not only culled the news, but often took a hand in supplying the sick and wounded with fruit, tobacco, and delicacies How quickly the reporters sniffed the latest news, I learned in Porto Rico I arrived from Arroya in the harbor of Ponce, August 13 Rumors of peace were rife for a number of days

The *Herald* dispatch boat, then in the harbor, got up steam at about 3 o'clock in the afternoon Soon the little craft put to sea, and I watched its course with intense interest I said to my friends, if the boat after leaving the harbor, turns in the direction of Arroya, it means war, if in an opposite direction toward New York, peace has been declared The proud little steamer turned its nose toward the United States and made a bee line for New York It was not until the next morning that the welcome news reached headquarters This is only one of the many instances in which the reporters came in possession of the latest news before they reached the officials The reporters were also instrumental in exposing many irregularities and defects of the military service from head quarters in Washington to the seat of war I have no doubt that many wrongs were corrected under the pressure of the press

It is not strange that many of our influential newspapers went a little too far in representing the grievances of the soldiers and in criticizing the action of departments and officers A tinge of sensationalism is common more or less to all of our great dailies ' Interviews that never occurred will continue to appear as long as the reputation of a reporter depends largely on his ability to satisfy the cravings of morbid curiosity The statements made to reporters are always susceptible to more or less reconstruction Again, it must be remembered that some men in the army, as elsewhere, are likely to exaggerate the true conditions, believing that by doing so, their services will be the better appreciated As the result of my own observations, I can say without fear of contradiction that the best soldiers do the least grumbling The most heroic and patriotic soldiers have the least to say of what they did and in relating hairbreadth escapes It is the drone that does the complaining, and who rides in ambulances, and overcrowds the hospital, and puzzles and vexes the hard-working doctor To the credit of the armies of invasion I must say that I heard but few complaints when the days were darkest and the food scantiest One day I visited the fever camp near the division hospital of the army before Santiago, where I found two hundred patients literally lying in the mud, with nothing but a wet blanket, most of them under a shelter tent, some of them even without this slight protection against the pouring rains Food was of the plainest kind, yet little or no complaint here The men expected hardships, and when they came they were not disappointed Grumbling became more marked and widespread with the progress of the war, after the men had become worn out by the campaign, and homesickness had gained a firm foothold The severest complaints have originated with camp followers The Medical Department has been criticized repeatedly, and yet it would be found very difficult to find among the returning soldiers any one who would be willing, or who would have reason to complain of the treatment he received at the hands of medical officers In case of war, the machinery of our government is a very complicated one The executive power of the Surgeon-General is indeed an extremely limited one Everything of importance has to pass through the hands and by sanction of the Secretary of War The Secretary of War is a busy man in keeping track of what is going in his department outside of the Surgeon General's office On the other hand the Medical Department depends entirely on the quartermaster s department in forwarding and distributing medical supplies No wonder that many collisions between these departments occurred during the present war Our experience has taught us in a most forcible way that the Medical Department should have charge of everything pertaining to the sick and wounded, in order to accomplish that for which it is intended The Secretary of War is not supposed to have any knowledge of medicine or surgery or other wants of sick and wounded, and yet the Surgeon-General is powerless in the execution of his orders without his co-operation If the forwarding and distribution of the medical and hospital supplies were directly under the control and management of the Medical Department we would have heard less of well-founded complaints of the scarcity of medicines and hospital supplies To make a department strong and efficient it must be independent It was not difficult to foresee when this war broke out that the greatest danger the troops had to expect was disease and not the Spaniards The importance of the Medical Department was never more keenly apparent than at the present time, and yet what was done? The highest official in the Medical Department is a Brigadier-General, and only five medical officers with the rank of Colonel, and seven Lieutenant-Colonels For the army major-generals were in abundance, brigadier-generals by the dozen, and colonels were turned out by the hundreds Many of the brigadier generals in brand new uniforms and glittering staffs never found a command, but their names remained on the pay roll just the same Many of our newly fledged colonels could not handle a musket to save their lives and some of them even attempted the unusual feat of mounting the horse from the right side In the face of all these appalling defects of army service the brunt of criticism continues to fall on the Surgeon General and his hard working officers in the field Much has been said of the mismanagement of Camp Wikoff Considering the limited transportation facilities, and the fact that in less than three weeks more than 3 000 patients have been cared for, it is a source of gratification that so much has been accomplished, largely through the energy of the Chief Surgeon, Colonel Forwood, and Majors Brown and Heitzman A corps of more than one hundred female nurses, including fifty Sisters of Charity, do the necessary nursing with a will and efficiency that astonish the many visitors The hospital tents go up like mushrooms, day after day, and at the present time 2000 patients are well sheltered and well cared for No lack of medical supplies at this time The surgical ward in my charge was completed today and is already crowded with patients The liberal contributions sent here by different relief societies supply the sick and well with an abundance of delicacies of all kinds The diet of the convalescents is luxurious, much better than what is furnished by the officers' mess The Red Cross is doing excellent work here, as elsewhere, in the distribution of clothing medicines and delicacies Mrs A Tscheppe who represents a relief society of New York is a familiar figure among the soldier patients and has been of much service in adding to their comfort and speedy recovery Most of the patients are suffering from [illegible] typhoid fever or dysentery The number of de[illegible] average from ten to fourteen daily, a [illegible] ege considering the number of pat[illegible] camp The patients here enjoy f[illegible] ing and excellent treatment, all of which will be conducive to rapid recovery The conditions here for the successsul treatment of the fever cases are, in my opinion, far better than in any of the large hospitals in cities It is to be hoped that the entire camp will be vacated in from four to five weeks, as after that time the soil will be thoroughly infected, in spite of all precautions, and the indigenous spread of typhoid fever would follow as an unavoidable sequence The surgical work consists in the treatment of large abscesses, occurring in patients whose general health has been undermined by disease, or the hardships of the campaign, and operations for hemorrhoids and rectal fistula Unjust and unnecessary criticism has a demoralizing effect on those directly or indirectly concerned It is prone to intimidate and confuse those who are criticised and embolden those who look for undeserved sympathy In this camp there is no further ground for complaint of any kind It is generally known that the Medical Department was not consulted in locating the camps For reasons known only to those in power, the camps were selected regardless of sanitary conditions Our troops have been exposed to malaria since they left the State camps, and almost every man shows evidences of more or less malarial poisoning As the essential cause of malaria enters the body by inhalation, malaria could not be avoided as long as the camps were located on a soil which breeds the plasmodium Typhoid fever made its appearance in the State camps and followed the army to Chickamauga, Tampa, Alger, Cuba and Porto Rico It is a repetition of what has happened during all campaigns under similar circumstances Let the national cry subside now and let the press and people await the results of a thorough investigation by Congress, which will place the responsibility for any mismanagement where it belongs The Medical Department courts such investigation, fully confident that the blame will be fixed outside of its legitimate jurisdiction

Camp Wikoff, Aug 31, 1898

OUR RELIEF SOCIETIES

BY N SENN, LIEUT COL U S V

CHIEF OF OPERATING STAFF WITH THE ARMY IN THE FIELD

War, pestilence, famine, floods and other great national calamities, are the most reliable tests to bring out the true philanthropic spirit of individuals as well as of nations- The good Samaritan is to be seen everywhere under ordinary conditions on his errands of mercy, following the footsteps of his Master in bringing comfort to the poor, the sick, the maimed and the oppressed, but his energies are taxed to the utmost, and his work is appreciated most keenly, when the masses are in distress The American people are noted for their charitable disposition, and have gained a well-deserved reputation for humanitarian work Our numerous ideal charitable institutions speak for themselves Many national catastrophes have demonstrated the liberality and good-will of our people The War of the Rebellion furnished an interesting object lesson to the outside world of the way in which patriotism is estimated here During the war just ended many different relief societies have rivaled with each other in supplying our soldiers, sick and well, with many comforts of life beyond the limit of the government supplies The government itself set a noble example by sending to the camps and the invading armies all kinds of supplies, unparalleled in quantity and quality in the history of the country I am sure no one regrets more keenly than the government officials that these liberal supplies did not always reach their destination in time The work of the many auxiliaries corrected many of these defects Individuals as well as organized societies have labored incessantly and faithfully in coming to the aid of the government, in furnishing the troops with underclothing and delicacies usually beyond the reach of armies when engaged in active warfare Miss Anabel Clarestes, a little girl in Lagrange, Ill, has been busy ever since the war commenced in preparing and sending to camps and the front home-made jellies, the product of her own hand She had no difficulty in collecting money to purchase the necessary materials, but it was left for her to labor in the humble kitchen to prepare the incomparable delicacies for the soldiers in the field This little American girl is a heroine worthy of the praise and admiration of the returning heroes who have been benefited by her modest, unselfish work Many a patriotic woman, unknown to newspaper notoriety, has done her share in minimizing the sufferings of this war It was not an uncommon thing for officers to receive a box containing the contributions of some female friend of the army who sent all she could spare for the alleviation of the troops in the field In many such instances the name of the benefactress remained unknown to those who benefited by her donation I have opened many such boxes, containing as a rule underclothing, bandages, reading and writing material, towels, handkerchiefs, and a few jars of jelly or canned fruit The soldiers who were made the recipients of these gifts felt that they were remembered at home, an assurance which contributed much in intensifying their patriotism and in sustaining their courage under the most trying circumstances The intense interest manifested by the government and the people in the care and comfort of the returning army remains unequaled in the history of our country Every soldier was met with a reception given to an intimate and long-looked-for friend The sick received the most tender care from all sides, and the well were given food that reminded them that they had reached home The hospitals and many private houses threw the doors wide open to receive those who required medical treatment Transportation home was made easy and comfortable by the active intervention of thousands of friends who were strangers when the troops left for the seat of war In all large cities committees were organized to look after the comforts of the returning troops In short, it may be safely stated that no army ever received a more enthusiastic, kind and cordial reception than the troops that have reached us from the seat of war

RED CROSS SOCIETY

Miss Clara Barton, President of the American Red Cross Society, has performed her onerous duties during the entire war with a devotion and earnestness that merit universal recognition at home and abroad She has been tireless in her efforts to bring comfort to the soldiers at times when her services were most needed The *Texas* and the little steamer *Red Cross*, under her command, made their appearance at Siboney at a time when outside help was most appreciated Ice, medicines, dressings and hospital supplies were freely distributed among the sick and wounded

After the surrender of Santiago the *Texas* was the first vessel to enter its harbor on its errand of mercy in bringing food for the hungry Cubans and delicacies for the sick of the victorious and vanquished armies The Red Cross Society established supply depots in all of the large camps and the good work done everywhere will live in the memories of all who were engaged in the conflict Miss Barton has the confidence of the American people and she has sustained it through the present war by the thoughtful and timely distribution of the innumerable and liberal donations to the society she so well represents An appropriate idea of what this Society has done can be gained from the fact that in Camp Wikoff alone two thousand dollars of supplies are distributed daily Miss Barton has been assisted in her widespread humanitarian work by a large staff of physicians and nurses who came to the relief of the medical officers at times when their services were most needed After peace was declared, Miss Clara Barton immediately sailed for Havana to bring much-needed aid to the starving reconcentrados of the long-besieged city, while her numerous helpers continued their faithful work in the home camps The work of the Red Cross received the moral and substantial support of the charitably disposed citizens throughout the United States and liberal donations from abroad Recent experience has again demonstrated that this society is the most important auxiliary in war as well as other natural disasters in bringing prompt relief to the sufferers

WOMEN'S PATRIOTIC RELIEF ASSOCIATION, NEW YORK

This benevolent Association has extended its work from the camps to the needy families of soldiers who enlisted and went to the front, leaving families behind them, worthy objects of well-deserved charity It was founded in the City of New York at the outbreak of the war, at the residence of Mrs Egbert Gurnsey, with Mrs Howard Carroll as president and well-organized committees and advisory board, consisting of prominent business and professional men The Association has provided food and house rent, as well as medical attendance, monthly, to no less than 2444 families A free eatinghouse was established at 711 Eighth Avenue, where these families received food and clothing Mrs Charles Carroll, a member of the Association was made president of the Naval Reserve Relief, and by contributions and a garden party given at her residence in New Brighton, Borough of Richmond, the sum of $2500 was secured, which was expended for the benefit of the New York Naval Reserves This special function of the Association did much for the comfort and efficiency of this otherwise neglected branch of the military service The hospital work of the Association has been under the management of Mrs Charles Carroll, Mrs Adolph Tscheppe and Mrs Seymore The ladies of the Association, with Mrs William McDonald as chairman, gave an outing to the convalescent soldiers from the different hospitals in Central Park, which proved to be one of the most memorable occasions in the annals of the history of this famous park Mrs Charles Carroll and Mrs Tscheppe erected a tent in Camp Wikoff when the soldiers from Cuba commenced to return, and have been busy in distributing without any red tape an enormous amount of most valuable contributions among the sick and convalescents Their donations of different stimulants and artificial waters have proved most acceptable and timely From this tent ice cream has been furnished daily A special messenger has done excellent service in distributing mail and in looking up soldiers inquired after by anxious relatives So fertile have been the resources of this modest little tent that it has been designated "The Gold Mine" Mrs Tscheppe represents the ladies of the "Liederkranz," and her popularity among the Germans of New York has brought not only the most liberal donations but likewise cash in large amounts Only the other day she received from a single source a check for $500, which she was asked to use at her own discretion in the care of the sick and convalescent in the camp The German press of New York has used its influence in supplying Mrs Tscheppe with ample means on her errands of mercy

ILLINOIS ARMY AND NAVY LEAGUE

This relief association was organized soon after war was declared It is composed of representative men and women throughout the State of Illinois, with headquarters in Chicago The secretary, Dr F H Wines, had an extensive experience in dispensing charity throughout the War of the Rebellion, and was consequently well prepared in assuming the laborious and trying duties of his office While it was the principal intention of the association to look after the interests and comforts of the State Volunteers, many of the contributions reached soldiers outside of the Illinois troops The State of Illinois, and the City of Chicago in particular, have been very active in minimizing the inevitable sufferings incident to active warfare by sending to the camps and the front large quantities of the most desirable articles of diet, delicacies, underclothing and medicines The League made special arrangements for transportation at reduced rates, so that the donations reached their destination promptly and at small expense The League has had from the very beginning a handsome bank account, and cash was sent to different points for the purchasing of the most necessary articles The citizens of Illinois will have the satisfaction of showing that by concerted action of the members of the League the work of charity and benevolence has been accomplished in the most satisfactory manner

MASSACHUSETTS VOLUNTEER AID ASSOCIATION

There has been an impression prevailing among the regular troops, that while the soldiers of the regular army have fought the hardest and have been subjected to the greatest privations, they have not received the recognition to which they are entitled and have been more or less ignored by the different relief associations There is undoubtedly some truth concerning these statements The Massachusetts Volunteer Aid Association has recognized the validity of this complaint, and has directed its surgeons toward correcting the oversight The work of this association in this direction has been particularly notable in Camp Wikoff A number of ladies representing the Association came to the camp and have done all in their power to render the soldiers belonging to the regular army comfortable and happy

A light diet kitchen was established, provided and equipped at the First Division Hospital in charge of Major Wood in conjunction with the Red Cross Society, under the superintendence of Mrs M H Walker The kitchen is an ideal one and is [illegible] by a competent chef Mrs Dininger

ger The bountiful donation for the sick of the Regular Infantry Division was brought to the camp by Mrs Leach, wife of Major Smith S Leach, of the Engineer Corps of the Regular Army, and was contributed by the ladies of New London, Conn , and the Pequot Society It consisted of a well assorted collection of soups, eggs, lemons, oranges, butter, crackers, sugar, barley, cocoa, farina, beef, ham, corn-starch, codfish, breakfast food, chocolate, gelatin, tobacco, pipes, keg of whisky, writing and reading material, towels, pajamas, night-shirts and underclothing The light-diet kitchen is one of the attractions of the camp The relief societies that I have mentioned are only a few of the hundreds organized throughout the United States for the same purpose, notably among them the "Daughters of the Revolution" and the "Colonial Dames," all of which did their good share in alleviating the sufferings of our army in camp and at the front The charity that has been practiced so bountifully and so generally during the present war, must satisfy our victorious army that the patriotism they carried into the field has been cultivated at home in words and action to a degree and extent unparalleled in the history of the world War in a just cause begets patriotism, and nothing can demonstrate this more clearly and forcibly than our experience in the field and at home during the last five months

Camp Wikoff, Sept 8, 1898

SOCIETY PROCEEDINGS

Society of Ophthalmology of Paris.

Meeting of July 7, 1898

[Translated by DR FLAVEL B TIFFANY, Kansas City, Mo]

M BOUCHERON, vice president, in the chair

M A DARIER presented a paper on

SOME THERAPEUTIC INDICATIONS FURNISHED BY THE BACTERIOLOGIC EXAMINATION OF CONJUNCTIVAL SECRETIONS

Several years ago, a short time after the works of Neisser, I made a series of researches in the endeavor to determine under what conditions the gonococcus produces the grave, virulent form of ophthalmo blennorrhea During two years I submitted to microscopic examination the secretion of almost all the conjunctivites who presented themselves at the clinic of my master, Abadie I was able to acquire thus the conviction that there is no true purulent ophthalmia without gonococci but all gonococcic ophthalmias are not equally virulent There are involved special questions of individualities both on the part of the patients as well as upon the part of the microbes themselves Now the microscopic examination gives us only an approximate indication, which, moreover, the clinical observation, for a long time practised, procures us in a degree equal if not superior So for several years I have renounced as a basis for therapeutic indications, the searching for the pathogenic microbes from the secreting affections of the conjunctiva I would not say as much of the pseudo membranous conjunctivitis in which the serotherapie is of a wholly different action, according to whether one has to do with the Loeffler bacillus or with streptococcus Now at this moment I am very greatly interested in the study of the therapeutic efficacy of a new salt of silver, the protargol The results which I have obtained from this agent are so favorable that I could only confirm the conviction by bringing irrefutable anatomic and clinic proofs, so I caused to be undertaken by Mr Valençon, my chief of clinic, a series of microscopic researches for confirming the diagnosis clincally put forth From these studies, which will very soon be given, in an inaugural thesis, I can already draw the following conclusions, which are, moreover, the very same which I had already put forth from simple clinical observation

1 Acute catarrhal conjunctivitis characterized by the presence of the bacilli of Weeks is cured generally in two or three days by the daily cauterizations of protargol

2 Subacute conjunctivitis with diplobacilli (of Morax) is at first rapidly ameliorated, but relapses are so much the more frequent in proportion as the time between the cauterizations is extended Moreover, at the end of a certain time, it comes about that, as with the nitrate of silver, a sort of accustoming to it, and the action of the medicament becomes, so to say, null and void It is necessary to change the treatment Following Mr Morax, I have tried the sulphate of zinc, but I have not been very well satisfied with it On the other hand I have been well pleased in these cases with the use of the acetate of lead, and with ichthyol 1/10 whether in solution or pomade

3 Gonococcic purulent conjunctivitis seems to be the affection called upon to draw forth the most brilliant results from the protargollic medication I sought to give the reason for this in two previous works (See the Clinique Ophthalmologique, 1898, Nos 1 and 6) Up to this time in all the purulent ophthalmias which I have treated for seven months by protargol I have not seen one in which the suppuration has not been dried up at the end of a few days by bi daily cauterizations, and that, too, in the most virulent forms But if one ceases the treatment before fifteen days the suppuration reappears

4 In two cases of acute pseudo membranous conjunctivitis, non diphtheretic, the protargol, contrarily to nitrate of silver, has led in three or four days to a complete disappearance of the false membranes What effect would be obtained in the forms truly diphtheretic? I shall occupy myself ultimately with blepharo conjunctivitis with trachoma and with dacrycystitis

Mr VALUDE—Gonococcus does not always produce the same form of ophthalmia I observed lately in a family of five cases one only presented a grave purulent conjunctivitis, the others were only affected in a slight degree, and all, nevertheless, had gonococci in the secretions It is then very important to find a means of diagnosticating the gravity of the affection, and this is what I hope to find in the researches of Dr Darrier

Mr SULZER—The gonococcus is not the sole agent capable of producing purulent ophthalmia, as the remarkable descriptions of Larrey on the subject of Egyptian ophthalmia (seasonable or climatic gonococcus) prove

Mr PARENT—I am surprised that Mr Darrier employs still in certain grave conjunctivites (and consequently susceptible to ulcerations) the solution of acetate of lead, which exposes to metallic deposits not only upon the ulcerated parts but even in certain cases upon the conjunctiva, where it is deposited under the form of little grainy particles Then, too, when our therapeutic arsenal is so rich in astringent and caustic substances, of what use is it to employ acetate of lead, which presents such inconveniences? When one speaks of purulent conjunctivitis, it is necessary in point of view of the gravity and the efficacy of treatment to make a difference between the adult and the baby In general the latter is less grave and not so liable to corneal complications It is then, for the more rapid cure of blenorrheal ophthalmia of the adult that we must establish the superiority of protargol over other treatment, and especially over nitrate of silver For, as to purulent ophthalmia of the baby, one may cure it (if the child is cared for immediately) by many different medications, and that with sensibly the same results Another important point to know is the following Does it dialyse or diffuse in the conjunctiva more deeply than nitrate of silver, and above all than of silver (naissant)? An excellent therapeutic agent recommended about fifteen years ago by Dr Sedan, the iodid of silver (naissant) is formed in the cul de sac, even by the double decomposition of alkalin, iodin and salt of silver introduced into the cul de sac, by means of two glass bipets In the point of view, especially, of the dialysis or of the thorough penetration of the deep layers, this iodin d'argent (naissant) presents some advantages, and I call the attention of Mr Darrier to it that he may experiment comparatively with protargol

Mr SPEVILLE—I have employed protargol only in catarrhal ophthalmia, and have obtained excellent results from it in such cases Purulent ophthalmia of the new born is not so benign as M Parent would have it, and for that I have seen recently two cases of babes treated with free washings with permanganate, who came back to me with both corneæ quite gravely compromised

Mr MORAX—It is very easy to convince one's self that all conjunctivites with purulent secretions are not due to gonococcus The conjunctivitis produced by the bacillus of Weeks often presents a purulent secretion It may even be accompanied by corneal lesions, as I have demonstrated, and on this subject I recall the case of a patient who had been attacked by an intense, acute contagious conjunctivitis with the bacillus of Weeks, which presented from the very first days of affection, and before the beginning of treatment, quite a grave corneal lesion, since it left after it a central leucoma, and M Darrier had to make ultimately an optical iridectomy The eyes of this patient had objectively the aspect of a purulent conjunctivitis, but I repeat we had not to do with the gonococcus, but with the bacillus of Weeks I believe that I have demonstrated that the classification of conjunctivitis based solely upon the objective aspect of secretion was erroneous We may make clinical diagnosis of the different conjunctival infections, by basing not only upon the objective aspect of the inflammation (as has been the custom), but also upon the commemoratives, the evolution, in other words, upon the whole assembly of the symptoms and not upon one single sign, so variable as the aspect of the anatomical lesion I am surprised that Mr Darrier has not succeeded in curing subacute conjunctivitis by sulphate of zinc The solution $^{1}/_{10}$ has the disadvantage of provoking a quite intense irritation, but the patients who can tolerate it are rapidly cured In very sensitive patients I replace it by the pomade of ichthyol I have only a very short experience with protargol, which in subacute conjunctivitis seems to me to be insufficient, as likewise nitrate of silver

Mr KOPFF—I rise to support what Mr Parent has said on the subject of the danger presented by the salts of lead in ocular therapeutics I have also had opportunity of seeing a certain number of patients treated by acetate of lead, who presented some plumbic incrustations upon the cornea and conjunctiva In presence of results of this kind we must consider acetate of lead a disastrous agent and proscribe it from our therapeutics As to protargol, I have not experimented with it, but I ask myself why we seek other medicaments when we have nitrate of silver at our disposition, which is the true specific of purulent ophthalmia of infants I have had the opportunity of seeing a great number of purulent ophthalmia of infants in the clinic of Mr Galezowski, who treated them all by his method of bi quotidian cauterizations with nitrate of silver $^{1}/_{10}$ The results are always rapid and excellent, cure is the rule when the infants are brought at first, before corneal complications I employ, also, at St Joseph's hospital, Dr Galezowski's method, and I have only to congratulate myself with its results That is why I do not see the necessity of seeking other medicaments, since the nitrate of silver, well and timely employed, has as sure action as possible Has Mr Darrier employed protargol in blenorrheal ophthalmia of adults?

Mr DARRIER—If I have not entered upon more details concerning different pathogenic agents of conjunctivitis it is because I wished to confine myself to the province of daily practice I know that purulent ophthalmia may be provoked by other microbes than the gonococcus, but today, clinically, three forms of conjunctivitis are established, they are Blenorrheal ophthalmia, acute catarrhal conjunctivitis of Weeks which, as Mr Morax told us, may be accompanied by ulceration of the cornea, and finally sub conjunctivitis with diplo bacilli of Morax It is upon these three forms only that my actual work bears I reserve for later study, diphtheritic conjunctivitis, trachoma, etc Certainly, I would not arraign nitrate of silver We ought to have for this product the gratitude which we owe to an old servant who has rendered us signal services, in spite of his faults, with which we have in the end familiarized ourselves But it is of the debutants of those who do not yet understand the delicate handling of this agent caustic in the highest degree, that we must ask their opinion on this subject Many of them will reply to us that it is a sword with two edges, which may do as much harm as good How many corneal ulcerations, how many productions of conjunctival false membranes have had for real cause cauterizations too energetic and too untimely? Well, these inconveniences do not exist with the proteinit of silver The solutions of this salt form a mucilage, the more onctious, the more they concentrate Applied upon the mucous membranes, there is very little irritation, as they do not coagulate the albumins neither are they precipitated by them, they impregnate and penetrate the epithelial cells, carrying into the depths of the tissues the bactericidal action of the argentic preparations Nitrate of silver, on the contrary, applied upon the conjunctiva produces a destruction of the epithelium, while at the same time it is precipitated from its solutions, which limits its action to the surface of the mucous membranes I have given up entirely weak solutions of protargol, and I no longer employ for cauterization with the brush any except the following solution Protargol 5 gr, distilled water 10 gr Let it dissolve spontaneously This solution is of syrupous consistency, adheres to the brush, and does not drop upon the linen and upon the vestments The cauterizations are made once or twice a day, and in the interval I instill three or four times, one or two drops of collyrium, 5 per cent., in order to sustain and prolong the effect of the cauterization made with the brush. Thanks to this treatment, regularly and promptly applied all the conjunctivites due to gonococcus and to the bacillus of Weeks will be promptly cured, those, on the contrary, which are due to the diplo bacillus of Morax will be rather respondent to the sulphate of zinc or to ichthyol For my part I think that until the discovery of the anti gonococcic serum we must consider the salts of silver as the most active against purulent ophthalmia, and it is our duty to seek that which with an equal efficacy shall present the greatest innocuity

Mr BOUCHERON—Is it the silver which acts specifically is it the acid of the salt? According to what we have just heard said by Mr Darrier it would seem that the protargol, which is not painful, would act everywhere by contact rather than by depth (penetration)

Academy of Medicine, San Francisco

At the meeting for the month of August, Dr J Henry Barbat presented a case of tubercular peritonitis in a child of fifteen months The child had exhibited only the symptom of abdominal enlargement with ascitis The fluid was not freely movable in the abdomen, but was sufficiently so to indicate its presence There had previously been a neoplasm of the skin on the chest, posteriorly, which had been removed when the child was about nine months old, this showed a microscopic appearance strongly resembling sarcoma There was a difference of opinion as to whether the abdominal tumor was a sarcoma of the spleen, or abdominal tuberculosis Operation revealed the nature of the disturbance Three months after the operation the child was still doing well Dr Douglas Montgomery said that he had seen this child in consultation before the neoplasm was removed, and had examined specimens of the mass and found they were very much like sarcomatous tissue He was therefore of the opinion, when he again saw the child after it had developed the abdominal trouble, that the latter was caused by a recurrence of the growth previously noted on the skin Dr E E Kelley reported a case of similar trouble occurring in a child three and one half years of age, on which he had recently operated, but without so good a result as in the case of Dr Barbat. The case of Dr Kelley was, however, somewhat different in that in Dr Barbat's there was a considerable amount of ascites in the abdomen, but in his case there was practically no ascites, the disease being of the fibrous variety and the whole abdominal viscera were practically glued together The peritoneum was thickened as much as an inch in places by this fibrous material The feces, examined for some days before the operation, showed tubercle bacilli in very great numbers As in Dr Barbat's case, the abdomen was treated to a stream of oxygen while open, but the result was as bad as had been expected, for the child died on the following day Dr Montgomery reported that he had examined some of the tubercles in the case reported by Dr Barbat, but that he could not find any tubercle bacilli, this did not show that there were no bacilli there, but that they were few if present Dr H M Sherman mentioned a somewhat similar case that had occurred in his practice recently There was slight enlargement of the abdomen, somewhat disturbed digestion, slight temperature, but no tumor and no ascites For some time he was of the opinion that he had to deal with a case of disturbance resulting from intestinal infection, possibly due to malarial poisoning On consultation the question of tubercular peritonitis was raised and it was decided to open the abdomen The condition was found to be one of miliary tuberculosis Dr Dudley Tait mentioned two cases which had been operated on for some other cause, and the peritoneum found on examination to be the seat of tubercular peritonitis Both cases did well after the operation He called attention to the great discrepancy between the findings of this disease at operation and on postmortem and was inclined to believe that many cases of so called tubercular peritonitis were self limited and had a tendency to spontaneous cure He mentioned some recent experiments on animals as to the absorptive action of the peritoneum and its relations to germs of disease, the experiments going to show that the peritoneum has a very strong tendency to throw off bacilli Dr Kreutzman was of the opinion that the question of diagnosis was not made sufficiently clear, and that a large number of cases reported as tubercular peritonitis were really something else He certainly found that where there were tubercles containing tubercle bacilli, the disease proved inevitably fatal but where there were simply tubercles without the presence of bacilli opening the abdomen would often produce a cure The pathology, he urged, should be more clearly studied and all efforts made to eliminate the doubt which was now present when the diagnosis of tubercular peritonitis is mentioned Dr Mc Monagle said that in his opinion these cases were often benefited but never cured, that the tubercular condition once established the fatal termination was inevitable. The [illegible] operation of opening the abdomen was fo[illegible] ment for from five months to eight years in [illegible] case had he noted a cure He recognized [illegible] of the disease, one with ascites, miliary tubercles, and few or no bacilli to be found in the tubercles, the other, with no ascites, the formation of large amounts of fibrous tissue in the abdomen and the presence of bacilli, while the former class was usually much improved by opening the abdomen, the latter class of cases did not benefit from this procedure With Dr Kreutzman, he believed that the diagnosis was by no means always clear, and that tubercular peritonitis was frequently given as the diagnosis when careful pathologic investigation would show some other etiology Adults did better after operation than children Dr Kreutzman reported a case of "Diabetes and Carcinoma of the Uterus" He first reviewed the recent literature on the possible connection between the two diseases There may be three explanations of the occurrence of these diseases together in some subjects, the diabetes may be the cause of the disease in the reproductive organs, it may be the effect of this disease in the uterus or adnexa, the diabetes may simply occur in a patient already having some disease of these organs After considering these three possibilities, he reported a case of a woman of 60 years who had been referred to him some time ago He found that she was voiding large amounts of sugar in the urine, and that there was evidently a carcinoma of the cervix and of the body of the uterus On diabetic diet and treatment the amount of sugar rapidly decreased Operation was decided upon, and the uterus removed by the vagina, the abdominal route not being chosen for the reason that more time was required in that case, and the diabetic condition contraindicated a long anesthesia Recovery from the operation was very rapid and satisfactory, and three days after the operation the sugar disappeared from the urine and was not again present, except at rare intervals and in small amounts, for the remainder of the patient's life The disease recurred in the right broad ligament about six months after the previous operation and was rapidly fatal The operative feature of the paper was discussed by Dr Huntington of Sacramento, and Dr MacMonagle of San Francisco

PRACTICAL NOTES

Dilute Caustic Potash in Lupus —This dressing has been found so effective by Unna that he now recommends it as superior to all other dressings used to date It never smarts, and the beneficial effect is actually remarkable in some cases —*Semaine Méd*, July 20

Application of Formol —To preserve and harden the central nervous system with formol in situ, insert a trochar in the nasal cavity, open through the lamina cribrosa, and introduce the formol through this passage —*Munich Med Woch* from *Deutsche Arch f Klin Med* x, No 5

Gall stone Diagnosis —The *Deutsche Med Woch*, of August 4, contains a communication from Czerny's clinic stating that in forty cases of gall stones tested (with one exception), the amount of sugar in the urine was more than normal—0 4 per cent and over—and fell much below normal after the removal of the stones

New Hemostatic —The comelina tuberosa was prized by the Aztecs for its remarkable hemostatic properties, and the Mexican physicians have recently rescued it from the oblivion of ages They find that it arrests epistaxis immediately, even in severe cases of traumatism, purpura hemorrhage, etc Several observations are reported in the *Gaceta Méd* of July 14

Electric Conductibility of Antitoxin —It has been established from a comparative study of normal horse serum and antitoxin that the freezing point, the osmotic pressure and the electric conductibility are all diminished proportionately to the amount of antitoxin contained The electric test may therefore possibly prove useful in testing the curative value of antitoxin serum —*Deutsche Med Woch*, July 7

Gosio's Rapid Test for Arsenic —The penicillium brevicaute grows with extreme rapidity and a penetrating odor of garlic in the presence of arsenic Abba detected arsenic by this means in one hundred and fifty hides from India in less than twenty four hours He recommends it as the most rapid, certain and cheapest test we possess for the detection of arsenic —*Munich Med Woch*, July 12

Treatment of Trachoma with Iodin —R Roselli of Rome reports 78 patients completely cured out of 100, with nascent iodin generated by administering potassium iodid internally, and when the iodin begins to be eliminated in the lachrymal secretions, he paints the upturned lid with oxygenated water Another method is to apply to the lid a 1/15 solution of the potassium iodid and then apply the oxygenated water The generation of iodin causes a slight smarting at first, which passes away in a few seconds to five minutes —*Semaine Méd*, July 20

Somatose in Syphilis —In syphilis and mercurial cachexia somatose is warmly extolled by Professor Fournier in the *Journ des Mal Cut et Syph* for March He has found it extremely effective in restoring strength and appetite in the anemic condition and nervous troubles that frequently develop in the course of syphilis It is especially valuable in the anorexia caused by mercurial cachexia and in cases of ulcerative processes in the throat and mouth, preventing the ingestion of solid food —*Vienna Klin Rundschau*, July 31

A Useful Device —A stand to use in applying casts and bandages to the pelvis, hips, etc, that has been in use a couple of years at Halle, has proved so satisfactory that it is described and illustrated for the benefit of others in the *Cbl f Chir* of July 9 The patient's back rests on a solid wooden stool, 20 by 20 cm and 30 cm high, beyond which projects an adjustable support for the head A tripod slides on a rod extending along the other side of the stool and the pelvis rests in a von Bruns' saddle mounted on this tripod The body is thus supported in three places, while an assistant holds the feet The stand can be adjusted to fit either a child or an adult

Picric Acid Intoxication —Picric acid is now used in certain industries, and intoxications from it are becoming more frequent The principal symptoms are a yellow tint over the whole body and in the mouth, pain in the epigastrium, dryness of the throat, depression, anuria and continuous cephalalgia In a case described by P Schwarz in the *Vienna Klin Rundschau* of July 31, a workman drank twenty grams, but prompt lavage of the stomach and intestines, with a diet of milk, white of egg and lemonade restored the patient The prognosis is usually favorable, permanent disturbances have never been observed

Irreducible Inversio Uteri —Duret treats this with 1, incision of the posterior cul de sac, 2, a median, posterior, vertical incision in the entire uterus from the vaginal incision to the fundus, 3, reduction of the inversion, 4, the incision in the uterus sutured down to the isthmus 5, reposition through the vaginal incision, the lips of the incision protected by the forceps, 6, suturing the cervix from the isthmus downward The vaginal incision is drained and left open, with gauze tampons inserted to prevent possible retroversion His patient, a woman of 22, had no hyperthermia and left her bed the fifteenth day —*Journ des Sc Méd de Lille*, July 9

Salicylic Acid and Salol in Pneumonia —De Becker of Antwerp proclaims that salicylic acid will cure and abort pneumonia with no other medication Besides its antiseptic action on the lungs, it liquefies and favors the expulsion of the sputa to a remarkable degree He gives 10 cg to children, every one or two hours, adults, 50 cg every two to three, or three to four hours, watching the heart, and varying or suspending the doses as the desired results are accomplished (Quoted in the *Cronica Méd*, June 15) R Liegel also announces that he has been successful in curing seventy two cases of pneumonia with salol, 8 gm a day, always combined with 50 gm pepper mint water, 200 gm water, and 5 gm "bitter" or any other tincture He gives a little ipecac to loosen the cough, with ice to the head when temperature rises above 39 5 degrees C —*Vienna Klin Woch*

Journal of the American Medical Association
PUBLISHED WEEKLY

SUBSCRIPTION PRICE, INCLUDING POSTAGE

Per Annum in Advance	$5 00
Foreign Postage	2 00
Single Copies	10 Cents

In requesting change of address, give old as well as new location.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
No 61 Market Street (Occidental Bldgs), Chicago Illinois

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

This is obtainable at any time by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr Henry P Newman, 100 Washington St, Chicago, Ill, sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer or direct to the JOURNAL office.

All communications and manuscript of whatever character intended for publication in the JOURNAL should be addressed to the *Editor*, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 61 Market Street (Occidental Buildings), Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, SEPTEMBER 17, 1898

SPLENOMEGALY WITH CIRRHOSIS OF THE LIVER

In 1894 BANTI of Florence described a new type of disease, which has since been known as splenomegaly with cirrhosis of the liver, or as BANTI's disease. The various instances of this disease which have since been reported, particularly in Italy and in France, now offer a good opportunity to study its principal clinical and anatomical features, and in a recent article BANTI[1] summarizes the knowledge of the disease.

As regards the etiology it may be said that the real cause is entirely unknown. The disease develops especially in young people and in the adult, as yet not more than one case has ever been observed in the same family.

The clinical course is divisible into three stages: first, the anemic, second, the transition stage, and third, the stage of ascites.

First there is noticed an enlargement of the spleen; in quite a few cases it has been demonstrated that this precedes all other symptoms. The spleen may reach a very considerable size, it has a smooth surface, rounded edges, hard, and, as a rule it is painless. Then come symptoms of anemia of the usual character. The blood shows a corresponding diminution in the number of red cells and in the amount of hemoglobin; poikilocytes and microcytes have been observed, but nucleated red cells are said to be always absent. There is no leucocytosis, and the proportion between the different kinds of leucocytes is normal. There is no trace of swelling of the lymph glands. The temperature is usually normal, but occasional attacks of chills, followed by fever, may occur at irregular intervals. This stage of anemia usually lasts from three to five years, but it may run along for as many as ten years.

The transition stage is marked by changes in the urine, the quantity of which is diminished, while urates, urobilin, and often bile pigments, occur; a mild general jaundice develops, the digestive functions are disturbed. This period lasts only a few months and is followed by the stage of ascites, which develops slowly and painlessly. The liver diminishes in size, the jaundice increases, the general symptoms of anemia become worse, very often there is an evening temperature. The changes in the blood also increase and death usually occurs in from five to seven months.

The pathologic changes consist in, *a*, the enlargement of the spleen, the capsule is usually thickened; perisplenic adhesions are, however, rare. On section the surface is deep red, with whitish lines and round, white, and hard nodules, which correspond to the Malpighian bodies, and *b*, the interstitial process in the liver.

In the ascitic stage, the liver is small, granular and hard; in the transition stage the surface may be just a little uneven, and the organ of normal volume. BANTI has not yet had an opportunity of examining a case postmortem that died in the first stage, but in cases in which splenectomy has been performed in this stage, the liver presented a normal appearance. Ascites does not occur until the last stage. In all cases examined the splenic vein and the portal vein, from the mouth of the splenic vein to the liver, have been found covered with dried, elevated patches, very similar to the sclerotic plaques so often seen in the aorta. The lymph glands are healthy. In the third stage the gastro-intestinal tract presents the well-known changes characteristic of atrophic cirrhosis. The marrow of the long bones is red and lymphoid.

Histologic examination of the spleen has shown the following changes: A few Malpighian bodies have normal structure; in others the periphery is composed of normal cells, while the arteries are surrounded by a zone of varying width, sometimes occupying three-fourths of the extent of the body, which consists of thickened connective tissue with few nuclei. This connective tissue is homogeneous and hyaline, and presents small spaces or slits in which may be one or two compact nuclei. Toward the periphery of the body the spaces become wider and contain more cells, the connective tissue becomes thinner and at last there is formed a coarse network which resembles somewhat the normal reticulum. The walls of the arteries in the Malpighian bodies have [illegible] completely with this periarterial hyaline fibrous tissue. The extent of the sclerotic zone is greater the further the disease has progressed. In some cases [illegible] fibrous nodules are found, wh[illegible]

---

[1] Splenomegalie mit Lebercirrhose Ziegler Beitr xxiv p 21 [illegible]

Malpighian bodies These changes begin around the arteries, as has been demonstrated in the spleens from early stages of the disease, and they consist, as will have become clear from this brief description, of a hyaline degeneration of the connective tissue Irregularly-shaped, larger and smaller hyaline scales have also been observed, but their source and nature are not explained, in some cases thrombosis of the vessels of the Malpighian bodies has been found In the pulp the veins present, in the early stage, large cells upon their intima, so that the venous channels look in cross-section somewhat like gland ducts Similar cells may occur in the reticulum around the veins The network of the pulp is thickened, fibrous, of hyaline appearance, and the cells enclosed in the spaces are fewer than normal, but otherwise without any changes

The principal changes then, in the Malpighian bodies as well as in the pulp of the spleen, consist in a marked increase in the thickness of the reticulum, while the peculiar structure of adenoid tissue remains, hence the lesion has been labeled fibro-adenia by BANTI The exact genesis of this thickening has not yet been made clear

In the liver there is the usual interlobular proliferation of fibrous tissue characteristic of the so called alcoholic cirrhosis, but the process does not seem to reach the intensity of the latter disease In the marrow of the long bones which presents the characteristics of fetal marrow, the number of nucleated red corpuscles is not very great

BANTI has made numerous cultures upon a large number of different media, but without any results Microscopic examination of the blood, the spleen juice, and of the tissues have failed to demonstrate the presence of bacteria or other parasites

The only drugs which seem to have any influence for the better upon the disease are arsenical preparations, but the improvement is only transitory In three cases splenectomy has been performed by COLZI in Florence One patient died from independent puerperal complications, one young man recovered completely He was operated upon in the anemic stage, the disease having then lasted about six years The third patient, a woman, was operated upon between the seventh and eighth year of the disease At the operation the liver was found somewhat granular, but the patient recovered completely, and twenty-one months after the operation she presented no symptoms of anemia, or of disease of the liver

It is evident that this disease has nothing in common with LAENNEC's cirrhosis of the liver On the other hand, splenomegaly with cirrhosis of the liver, in the anemic stage at any rate, presents great similarity to a disease which is known in the Italian and German literatures as splenic anemia It might be claimed, for instance, that splenic anemia represented only a stage of splenomegaly The exact nature of the so called splenic anemia, and of another condition, or possibly the same condition under another name, namely splenic pseudoleukemia, remains very obscure, and the various conceptions of what is to be included under the term, or terms, are somewhat confusing, and BANTI is not able to clearly define the relation between splenomegaly with cirrhosis of the liver and splenic anemia or pseudoleukemia The only decisive means of differentiation would have to be sought in the etiology of the processes, which is as yet completely unknown in all three

BANTI looks upon a chronic intoxication proceeding from the spleen as the most reasonable cause of the anemia which characterizes this disease This view he finds is supported by the fact that when the spleen is removed the anemia disappears Furthermore, he looks upon the chronic sclerotic splenic and portal endophlebitis, which in the early stages is confined to the splenic vein, as indicating that poisonous substances are carried in the blood passing along this route He regards the cirrhosis of the liver as a direct result of the disease of the spleen If poisonous substances are elaborated in the spleen, then they are constantly carried through the liver and result in the end in hyperplasia of the connective tissue, in somewhat the same way as the poisonous substances absorbed from the intestinal tract in chronic alcoholism are supposed to produce typic atrophic cirrhosis Finally, BANTI calls attention again to the fact that the only curative measure known is the removal of the spleen

The literature concerning this interesting condition described by BANTI is not very extensive In the bibliography attached to BANTI's article, which is presumably complete, there are only ten references It is to be hoped that new cases may soon be described in American literature, and that the relation of splenomegaly with cirrhosis of the liver to splenic anemia and splenic pseudoleukemia may be more definitely established

A NEW PATHOLOGY IN EPILEPSY

Epilepsy, one of the oldest diseases of the nervous system of which we have knowledge, is, as regards its etiology, and particularly its pathology, practically but little known The names given it by the Father of Medicine, "sacred malady" and "malady of children," show in what light it was regarded by the ancients For centuries the most ridiculous and incredible theories were advanced by the best men of their time with truly commendable zeal, but real progress can not be said to have begun previous to the statements of reflex irritation advocated by MARSHALL HALL Since then decided advances have been made along many lines, due especially to the magnificent work of HUGHLINGS JACKSON, but even to this day authorities differ greatly as to causation in a vast majority of those afflicted Age, sex, heredity, insanity, organic brain disease, trauma, syphilis, chronic alcoholism of parents, must all be regarded as important considerations. Many curious facts in respect to etiology have been reported of late years; errors of refraction, especially astigmatism, are of common occurrence; compression of the carotids producing cerebral anemia, bradycardia, diabetes, the diminution of the toxicity of the urine previous to an attack, pressure upon an undescended testicle, all in a considerable number of instances by eminent observers. The rôle of trauma in the causation of epilepsy is too well grounded to be easily shaken, but undoubtedly too many cases are classed under this head. Almost every individual, whether epileptic or not, can give a history either known to himself or narrated by his parents or friends, of a fall upon the head during childhood or at some later period and yet but a small proportion of the population suffer from epilepsy. Probably only a small ratio of epileptics, not over 2 per cent could rightly attribute their affliction to this cause. There remains then the major portion of the sufferers, in whom the etiology of their affliction and certainly pathology, is obscure, that must be classed under the term—for want of a better—idiopathic epilepsy. For the clearing up of obscure points of this disease, too much attention has doubtless been directed to the nervous system, as is the case of insanity, with a passing over with but trifling consideration other pathologic conditions existing in the body.

For the study of epilepsy, both the clinical manifestations during life and the pathologic findings after death, there is probably no better place in the country than the Ohio State Hospital for Epileptics at Gallipolis. There are usually from six to seven hundred inmates, twenty to thirty of whom come to the autopsy table during the year. Lately a well appointed laboratory has been fitted up, and the research work placed under the able direction of Dr. A. P. OHLMACHER. The latter, in his researches into epilepsy, determined to examine not only the central nervous system, but all other parts of the body as well, with the hope that some constant pathologic lesion might be found upon which statistics of some value could be compiled. His efforts have been crowned with considerable success, as demonstrated by his report in the *Columbus Medical Journal* of July 19, "The Persistent Thymus and Other Morbid Anatomic Peculiarities in Certain Cases of Epilepsy." His studies comprise eighteen cases, in eight of which more or less constant pathologic features were presented. All the victims were in the young adult period of life. Six of the eight were undoubtedly grand mal, therefore "idiopathic." A curious fact is that three of the eight died suddenly. One other committed suicide and one died of exhaustion after an attack of mania. Four of the eight had attacks of mania at more or less regular intervals. The summary of his findings can be perhaps best stated in his own words: "Persistent and enlarged thymus gland, a pronounced enlargement of the intestinal and splenic lymph-follicles; a more or less pronounced hypertrophy of the lymphatic glands, and the lymphadenoid follicles of the tongue, larynx, trachea, esophagus, tonsils and even of the stomach; a narrowing of the arteries; an abundant development of fat and certain osseous changes indicative of old rickets. Not all the abnormalities comprehended in this summary were present in a single case, though the persistent thymus, with one or several features added, was constant." OHLMACHER, in conclusion, calls attention to enlarged thymus occurring in two other conditions, namely, "laryngismus stridulous" and "sudden death in adults with no assignable lesion," and lays special stress upon the sudden death of his three epileptics, in all of whom it might again be remarked that the thymus was enlarged. He regards the "lymphatic constitution" occurring in these three affections and the sudden dissolution that appears so commonly as more than a mere coincidence. It is to be hoped that other institutions will direct their attention to the findings of OHLMACHER, so that the great pedestal for the successful treatment of any disease, a morbid anatomy, may in this most obscure of affections be founded upon a firm basis.

BLOOD EXAMINATIONS IN SURGICAL AFFECTIONS

While medical men were glad to seize the opportunity of increasing the strength of their diagnoses by examination of the blood, the surgeon, until late years, has always held rather aloof, trusting more to the physical signs and constitutional reaction than to anything else. With the difficulty often accompanying the diagnosis of appendicitis, he at last became eager to accept any additional evidence that might be offered, and the hematologist has often been called upon for help. So frequent became these examinations in appendicitic affections that several important points, both in prognosis and diagnosis, have been fairly well established. As one would naturally expect, purulent appendicitis is usually accompanied by leucocytosis. This symptom is very common, and in a way may be looked upon as a good prognostic sign for this reason. If your diagnosis is reached by other symptomatology, and no leucocytosis is present the prognosis is bad. The size of the leucocytosis is of some importance. A count in the neighborhood of ten thousand means that the purulent collection is walled off from infecting the general peritoneal cavity, that the case, even if no adhesions have formed is a mild one or as hinted above the patient is in a serious condition the economy reacting very little if at all to the infection. The increase in the number of leucocytes may be looked upon as th

an army to resist invasion. On th

high leucocyte count is not neces

nostic sign, but this one point must be considered, whether or not there is a steady and progressive increase This latter symptom is a dangerous one and urges instant operative interference If after a leucocytosis has become stationary and, of a sudden with increased severity of the constitutional symptoms, we find a sudden increase or marked decrease in our count, we are safe in concluding that a purulent collection, once walled off, has burst its bounds and is invading the peritoneal cavity, the increase or decrease, depending, as mentioned above, upon the reaction or the reverse of the system to the increasing infection Many cases of appendicitis, especially where no tumor mass can be discovered, are confounded for a time with typhoid fever, on account of the abdominal pain and febrile reaction In the early stage the Widal test would not be of much value, but the presence of a leucocytosis would be in favor of appendicitis, unless the typhoid were complicated with pus formation, in which case the count would give us no aid If an attack of appendicitis is progressing toward a favorable termination, the number of leucocytes will fall steadily, so that the daily examinations of the blood in this disease are of the greatest service The importance of a leucocyte count will be the more appreciated when it is taken into consideration that the presence of this symptom alone will differentiate appendicitis from the various forms of disease and colics accompanied by pain in the right iliac region The one exception is pyosalpinx

A problem that has been puzzling surgeons for many years is what to do in the condition known as "shock" Of course the causal factors must first be considered The next important point is the question of concealed hemorrhage, so often the forerunner of shock If we know that such hemorrhage be present the indication would be to in some way reestablish the normal amount of fluid in the arterial tree, and the best way of accomplishing this is by transfusion of the normal (six-tenths per cent) saline solution On the other hand, if shock is due to compression of the brain, transfusion would work in most cases irreparable harm Whether or not blood has been lost in any considerable amount, can be absolutely determined by the blood count, in previously healthy subjects the number of red corpuscles and amount of hemoglobin being diminished in direct ratio to the amount of blood lost from the vessels The leucocytes are diminished but a short time, with the slightest reaction on the part of the system, leucocytosis, both relative and absolute is soon induced It is astonishing what an enormous amount of blood can be lost from the general circulation before death supervenes DACOSTA says that one half of the blood can be lost before fatal syncope comes on MIKULICZ, than whom no surgeon is better authority on hematologic subjects, advises never to undertake operation "when the hemoglobin is under 30 per cent," so that it is probable that he has had cases in which the blood has been below the limit of DACOSTA, and yet not have perished immediately

In malignant disease, blood counts and examinations have been reported without number Until lately, however, not much of any practical diagnostic value has been offered It has been known for some years that after an operation of any magnitude, involving the loss of some blood, some time elapsed before the hemoglobin percentage began to rise This interval of time was known as the "regeneration time" and was usually reckoned between two and three weeks In malignant diseases, as demonstrated recently by BIERFREUND, it is fully a week later before the hemoglobin begins to climb the scale, and at that never reaches the point it held before the operation, even though that point may show grave anemia

THE SANITARY RESULTS OF OUR CONQUESTS AND ANNEXATIONS

The addition of tropical territories and population to our national dominion has certain medical and sanitary bearings that are well worthy of careful consideration This statement does not necessarily imply that such additions involve any elements of national peril in a medical point of view, though that has been urged as a fact by those opposed to such territorial expansion, but simply that it enlarges the range of our national hygienic supervision and brings some sanitary problems more nearly home to us than was formerly the case Instead of involving new dangers the extension of our rule ought to eradicate existing ones to a large extent and favorably modify others where their complete avoidance is impossible Warm countries are commonly regarded as unhealthy, and they certainly have some special disadvantages in a hygienic point of view, but it is a fact that ordinary sanitary precautions are hardly anywhere so habitually disregarded as they are in every tropical region, especially by the whites there residing Dr MANSON and others have shown that most of the formidable disorders peculiar to the tropics are more or less avoidable, even by those who have no inherited or racial immunity, and that there is no good reason to assume that the white race can not flourish there, so far as their physical welfare is concerned

Whatever influence the United States may have over the future of Cuba, whether as a friendly or protecting power, or as exercising actual dominion, should be for the mutual good, and this is particularly true as regards matters of public health The sanitary reformation of Cuba will be for us an even greater blessing than its political redemption, for heretofore and up to the present it has been a continued threat of impending pestilence, solely on account of neglect of sanitary precautions and decent hygienic regulations With yellow fever endemic in Havana and Santiago, there will always be a chance of its introduction into our Gulf ports, and whatever arrangements are made as to the future of Cuba, it is the duty of our government to see that adequate guarantees are given that the there existing anarchy in sanitation is to be quickly and thoroughly abolished This will be a result of the war that will be well worth a large part of its cost

Porto Rico, as a territory of the United States will come directly under our laws and whatever dangers to health exist there can be met with our own resources It is said to be a comparatively healthy island for a tropical one, and it may be no serious sanitary questions will be raised

Much was said by the opponents of Hawaiian annexation about the danger from the leprosy infection, of which it is a center Whether this danger will be in any degree increased by annexation is open to question, our commercial and other relations have always been close, and especially so of late years, since the reciprocity treaty has been in existence Hawaii has been practically an American dependency for many years, and political union can not very materially alter the conditions So far as it can have any effect it should be for the better, as it puts matters under our own control and gives us the power to remedy any existing defects in hygienic conditions or sanitary laws That we can improve upon the present regime is perhaps doubtful as far as leprosy is concerned, as it does not appear that more precautions are taken anywhere against the spread of this disease, or a more thorough system of isolation carried out than is the case in Hawaii The fact, also, that there are only about a dozen white lepers in the settlement on Molokai and these presumably all that could be found in the islands, would indicate that the extension of the disease is almost exclusively among the natives, whose habits seem especially to favor its spread In any event the danger of leprosy infection to our people would seem to be slight, less indeed than from the Louisiana lepra focus, where a much larger number of whites appear to be infected In other respects Hawaii is certainly a healthy region and the white race appears to flourish there, aside from the leprosy question no serious sanitary problems are involved in its annexation

The Philippines which may also come under our rule, present the usual hygienic conditions of warm countries with large rainfall Some of the islands like Mindoro and a few others of the group, are notably unhealthy, and the uncultivated portions of some of the larger ones are also subject to fevers etc In other respects however, there seems to be no reason why with proper precautions Americans who may go there should not be as well cared for as anywhere else within the tropics If they come under our flag we may find that we have to meet some new conditions, but the sanitary problems will probably not be the most serious ones

The results of the war ought not, in a medical point of view, to be on the whole otherwise than beneficial, as it will put it in our power to remedy existing abuses, and it should not be anticipated that new ones will be created A decent military administration of Santiago has, it is said, already stamped out yellow fever in that city, where it has existed endemically, and a like result may be anticipated under perhaps greater difficulties in Havana and elsewhere

A STORY OF CHICKAMAUGA

Members of the AMERICAN MEDICAL ASSOCIATION have no doubt been troubled in mind during the progress of what we may now call the late war, by the continued attacks in the press on the Medical Department of the Army, from the Surgeon-General at the War Department and his officers of every grade in the general and division hospitals down to the gallant medical men who dressed the wounded under the fire of the Spanish sharpshooters at the crossing of the Aguadores river The sanitary conditions in the home camps have also been severely criticised, and the onus laid on the shoulders of the Medical Department The injustice of this criticism has led Major R STANSBURY SUTTON, Chief Surgeon U S Volunteers, to discuss with a free pen the conditions existing in the camps in Chickamauga Park (see p 650) It takes a man of large experience and mature mind to deal with these subjects, for some of them are of a nature so delicate that the average man would probably pass them over in silence because unwilling to suggest the existence of a stain on the moral character of any of the gallant young men who volunteered to carry our flag to victory Dr SUTTON charges much of the sickness that prevailed in the Volunteer camps at Chickamauga to the dissipation of the men It would probably be difficult to verify the alcoholic excesses by any official record, as men on pass usually sober up before returning to their commands, and the men reported as seen by the Doctor were probably all on pass Whether his estimate of the prevalence of venereal disease will be substantiated by the official statistics remains to be seen, but we recall the fact that these diseases were so prevalent in certain army corps camped near Memphis and Nashville during the Civil War that special military methods had to be adopted for their suppression The medical officers on duty with the ambulance corps at Chickamauga no doubt did their duty in drilling the men of the hospital companies in first aid and if they spent their leisure otherwise than in medical reading and study allowance must be made for the deteriorating influences of camp life The Red Cross and other national relief associations receive due credit [illegible] and the stories of cruelty and neglect [illegible] the newspapers are shown to be false

CORRESPONDENCE

A Grave Menace to the Public Health

New Orleans, Sept 8, 1898

To the Editor —Without entering into the unseemly wrangle that the Medical Department of the Army is engaged in, I would like to call the attention of the profession through its own Journal to two new diseases—new to the physicians who have spent their lives in the United States, but old to those experienced in diseases of tropical countries—I allude to tropical dysentery and tropical anemia, the former being due to the ameba, the latter to the ankylostoma duodenale Our soldiers returning to their homes along the many railroads that ramify in every direction over our country, are liable to infect the entire country with the germs of these two insidious and apparently, in their incipiency, ordinary affections If it be true, and I think every intelligent physician holds that view, that typhoid fever is pre eminently a preventable disease, and consequently its alarming prevalence in all of our camps is *criminal* and due entirely to ignorance, which has been said to be worse than crime, how much more than criminal is it for our medical department to aid and abet the incompetent war department in scattering broadcast over our fair land two of the most deadly diseases of the tropics? It is claimed with the amplest authority that every case of typhoid fever originating in a camp is due to the criminal neglect or ignorance of the medical officer, some colonel or major, in charge of that camp Now, without questioning the right of army surgeons, who, by the way, resent being addressed as physicians, to allow their charges to become infected with death dealing germs, I do protest as a civilian, a plain doctor, to their scattering these germs all over the country among civilians, who have no captains, majors or colonels to treat them I claim that one case of typhoid fever, amebic dysentery or tropical anemia traveling from Montauk Point to California, is liable to infect any or every stream between the Atlantic and Pacific that he crosses It is high time our distinguished Surgeon General warned the bargain counter politicians in the war department that such things must cease, and cease at once None know better the grave danger that confronts us than Dr Sternberg I beg pardon *General*, for calling you Doctor, but your reputation as a scientific, accurate physician is so well known that I had forgotten the measly little star on your collar Now the regular army, medical and lay, let no opportunity slip of finding fault with the volunteers and the civil surgeons, so let them bear the blame as they claim the glory in this matter, for let it be distinctly understood that none but surgeons in the regular army have a word to say about this matter The Secretary of War, if he consults any medical men, consults those in authority I hold that the time has come when the medical department of the army should be governed by common sense founded on mere known facts, facts known to the medical and lay world alike today

Today there are said to be cases of yellow fever in this section of the country Do we gather up all the cases and divide them up in all adjoining States? No The Marine Hospital Service establishes camps of detention for those who have been exposed to the infection and keep them there ten days before allowing them to invade healthy territory The sick are strictly isolated and kept so until recovery or death Eight hundred marines were camped for many weeks at Guantanamo and their health remained excellent, and why? Because the surgeons of the Marine Hospital Service not only understand preventive medicine, but they *practice it* Every man in that Service is qualified for the work he is assigned to The War Department seems to defy all known laws of sanitary science in pursuing a course diametrically opposite to that adopted by the Marine Hospital Service, as well as all State and municipal health officials All soldiers suffering from dysentery, anemia (tropical) or typhoid fever, should be confined in suitable hospitals and kept there as long as the microscope shows them capable of being a source of infection to others All their dejecta, urine as well as feces, should be subjected to sufficient heat to destroy germ life

All red tape should be brushed away, and instead of moving camp every time the camp becomes infected through the grossest neglect of all hygienic and sanitary laws, the medical officers responsible for such a condition should be removed on the ground of incompetency, and in their stead should be appointed men of known ability, men who are major generals in the warfare against filth and filth diseases In every large city on this continent can be found physicians who have spent years of their life in this branch of medicine The Government should employ such men at salaries commensurate with their ability Good physicians are cheap at any price, and our Government should promptly employ the best What would happen to the health officials of Chicago or Washington if 10 per cent of their population should be stricken with typhoid fever within sixty days? The residents of those cities could not conveniently change the location of the cities every sixty days, but they would most assuredly change health officials, who, in turn, would change the sanitary conditions

Before closing, I wish to state that this article was not written to criticize the army surgeon, for I know full well his worth, his faithfulness and his ability The gifted head of the Service needs no one to defend him His many contributions to medical literature entitle him to say with Horace "*Exegi monumentum perenniusære*" What I have written is purely in the interest of the public health of the nation I refuse in advance to enter into any controversy with bureau doctors, whose time is paid for by the government and hence worth nothing to them

"Facts are far superior to reasoning "—*Hippocrates*

Very respectfully, T S Dabney, M D

The Treatment of Typhoid Fever

Chicago, Sept 10, 1898

To the Editor —While much, of late, has been written on the treatment of typhoid fever, I feel that a brief statement of my experience may be of some value to others, especially as I seem to have met with greater success than anyone else whose reports I have read I have thus far hesitated to relate my experience, because of the fact that when I changed my location several years ago, to adopt a more exclusive practice, I destroyed some of my records However, I can recall at least twenty eight cases in my last four years of general practice, and I think there were more in that period But one can easier recall deaths than cases Two deaths occurred among my typhoid fever cases during the four years in question, but one of these two cases was moribund when I first saw it It was the case of a young man brought home from the pineries, suffering with the fever When I first saw him he was delirious, and he died two or three days later The other case was a middle aged man who was allowed to get out of bed frequently, but contrary to my instructions, and suddenly expired, although his condition had not been particularly alarming No postmortem was held

One of my cases of typhoid was a robust farmer, who recovered, but prematurely left home for a week to attend to some business He returned sick, having a premonition of pending death, with what I took to be diphtheria He died in a few days Postmortem revealed the intestines normal, but kidneys greatly congested Thus it will appear that in reality I only had one death among the cases which I treated from start to finish

My treatment had special reference to the following dangers: loss of vitality, germ breeding in the intestine, perforation and hemorrhage

The first evil was met by isolation in as quiet a room as accommodations afforded I strictly prohibited visiting by friends on penalty of my quitting the case Relatives were allowed to visit for a few moments during certain hours of the day I often had much fighting to do on this point, but I pushed my demand with severity and invariably won respect in the end A glassful of milk was given punctually every four hours, supped from a spoon When half the glassful was taken a few minutes' rest was given before the remainder was supped Sometimes a dose of lactopeptin or liq pancreatin followed the milk Grapes, if procurable, were allowed freely, as was also cold water to drink in small quantities at a time Every four or six hours, and sometimes oftener, the entire body was gently wiped with a soft piece of muslin dipped in lukewarm water containing a teaspoonful of bicarbonate of soda to the pint The wiping and drying was done in patches, and the proceeding was not only gently but patiently accomplished This process of cleansing and cooling had the effect of mild massage and was invariably refreshing if done *gently* and *slowly* Frontal headache was usually relieved by dipping a piece of muslin in a solution of cyanid of potash in laurel water (10 grains to the ounce) and laying it on the forehead for ten or thirty minutes

The second point was supposed to be met by increasing the flow of bile into the intestine with one to three grains of calomel twice a day Codein was given if griping was experienced The calomel was kept up until the crisis was over

The third danger seemed to be met by giving three or four drops of rectified turpentine every four hours, to diminish the gas in the inflated bowel and thus reduce the liability to perforation from distention of the bowel and the pressure of the gas on its ulcerated surfaces Kidney complication was watched for, but the turpentine was seldom suspended if the bowel was markedly tympanitic

The fourth point—hemorrhage—seemed to be forestalled by giving a dram, more or less, of the fluid extract of hamamelis every four hours About twelve years ago I read an article in the *British Medical Journal*, by Shoemaker of Philadelphia, on "Hamamelis as a Vascular Constringent, etc" I then began to use it in a variety of varicose and hemorrhagic cases and was so favorably impressed with it that I concluded that its constringent, astringent and tonic properties would be serviceable in typhoid fever, as a preventive of hemorrhage, if nothing more I therefore adopted the following prescription, which was only modified to meet the factors of the personal equation

℞	Spts Terebinth Rect	ʒi
	Spts Juniper	ʒss
	Fld ex hamamelis (P D & Co)	℥ii
	P acacia	℥iss
	Aq qs ad	℥vi

Sig —Dessertspoonful every four hours while awake

All the cases ran a moderate course and seemed to be abbreviated, as compared with my experience for ten years prior The diarrhea seldom called for interference Medicine and milk alternated every two hours, but were, as a rule, not allowed to interrupt sleep for two hours more if sleep continued that long The cases were mostly sporadic and mostly in the country Several families had three or four cases at the same time A few were fat, flabby women of very low physiologic tone

J Sanderson Christison, M D

The "New Interpretation of Operative Principles"—A Pertinent Question

Kansas City, Mo , August, 1898

To the Editor —What should be the attitude of the "science mind" in regard to discoveries and theories, revolutionary in their character and tendencies in medical science, in other words, the duty and obligation of the scientific physician in respect to "new interpretations of long accepted basic principles in medical science now being promulgated" Unfortunately our wording of the subject is wordy, we trust our discussion of it will not be found mere words It is said, history repeats itself Up to the beginning of the fifteenth century the Ptolemaic system was the accepted astronomic science All discoveries of new planets or fuller knowledge of known ones was adjusted to the recognized Ptolemaic plan of the earth as the central body Many "hitches" in the workings of the scheme and anomalies arose here and there and again and again, but they were silently ignored or explained on some hypothesis, or openly confessed as something needing illumination and elucidation This was the condition of astronomic science for many centuries Meanwhile patient investigators had been at work studying the difficulties that presented and the theories of explanation given Light dawned here and there, more rational, yet still crude, ideas were conceived, until at length Copernicus, gathering the converging rays of light, discovered the error of the ages and installed the sun as the central orb, and promulgated what has since been accepted and termed the Copernican astronomic plan With the sun as the center, all the planets fell into their natural places, and harmony and beauty reigned The disagreements in the various theories and hypotheses soon disappeared, untenable ones were discarded, and though there have been added by discovery new worlds to the system, and more exact computations of distance and of plane of orbit, etc , yet no absurd theories have been projected, no fanciful hypotheses have been conjectured, agreement and harmony have prevailed from that date, because, at length, a complete science of basic principles had been constructed

Notwithstanding all the acknowledged crudities and inadjustable inharmonies of the Ptolemaic theory, "It required one hundred years to develop a comprehension that any scientific advantage would accrue from a review of the alleged situation" (Dunham) So of course the new theory was ignored or ridiculed and combated, and only slowly, tardily and laboriously commanded, and finally obtained, recognition

The question underlying the inquiry with which this paper began, is, Will the scientific medical man ignore and neglect, or will he boldly face and investigate "A New Interterpretation of Operative Principles," which are to the last degree revolutionary and iconoclastic? It will not take a hundred years to develop a comprehension of the scientific advantage to be derived from a review of the prevailing theory of medical science That review has long been in progress A medical unrest has long been apparent Dissatisfaction with the old and long established views and principles has been stirring the minds of many for years Medical literature, especially as seen in medical journals, presents an aspect of confusion and fanciful speculation, the most absurd and groundless theories being entertained

The scientific mind asks, Why all this? and foundation principles are being examined The results of this will soon be apparent, in fact, are already appearing As voicing what we here surmise or affirm—impatience with the unscientific, dissatisfaction with the crude and imperfect, ambition for and attempt to reach the ideal—read the magnificent address of Dr Musser before the American Medical Association at Denver on "The Essential in the Art of Medicine" Polypharmacy and a blind following of precedent with any practice of the "art of medicine' not founded upon and suggested and also justified by the "science of medicine,' must certainly have received its death thrust from his well aimed dart

And now comes that to which we call special attention and which we confess aroused our question and suggested this paper—Dr Dunham's Lecture in The Journal of the American Medical Association of July 2 1898 "A New Interpretation of Operative Principles" This is a part only of the title, but abundant for our purpose The Operative Principles "A New Interpretation" of which is all Dr Dunham in his [illegible] esty claims, are as old as medicine itself, and are to be found in medical literature all down the ages to the present Yet the theory of medical teaching up to the present day is one of confusion as to the nature and limit of these operative principles A new, that is, a correct, interpretation has been sadly needed, and to the want of which may be charged the fanciful, erroneous and absurd theories and isms and schools of the past and alas of the present

The status of medical science as taught and accepted today justifies the following arraignment of its position 1 It is unsettled as to any consensus of view of the nature of vital force 2 It assumes that positive conclusions in regard to this essential point are impossible in the present condition of medical knowledge (Mandsley) 3 There is confusion as to recognized operative principles, because these are supposed to be vital and otherwise It is accepted that operative principle is inherent to and active within the vital doman, it is also assumed and understood that operative principles, from without become active within the human organism "Active medical principles, active causes of disease, may be introduced and take part in operating the human organism" (Dunham) Now here we run into a labyrinth of confusion For, back of the study of the nature of the forces which present disease phenomena, is the consideration of the nature of the forces which operate the machinery of life (Dunham) This is the question of vital force, of which, confessedly, there is at present no solution The most vital question in medical science of the hour is, as to the precise nature and limitations of the forces operative in the living organism Despite the fact of the acceptance—and assumption of their correctness for ages—of the medical principles stated, we must go over the ground again as to the nature of vital force Do all operative principles inhere in the vital domain or are there supplemental forces which can be introduced from without? Now here lies the serious error of operative plan, as set forth by Dr Dunham "The teaching of medico biologic science as being based on functions and operative principles derived from both within and without," while he maintains that true "medico biologic science is based entirely on the functions and operative principles, which originate and control all the activities of the human organism, physiologic, pathologic and therapeutic, and those arise from, inhere in and are confined to the human organism" There is no operative principle outside the vital domain which may be imparted or conveyed to it Drugs contain no operative principle by which disease can be removed and normal conditions regained They do not act In illustration take the law of physics "A body at rest tends to remain at rest" It remains at rest until some force outside itself moves it, but it has no "tendency" anyhow or anywhere, it is absolutely inert and forceless Drugs are inert and inoperative so far as any operative principle or force in themselves is concerned In the realm of nature the higher dominates the lower In the natural kingdoms, animal, vegetable, mineral, the higher is closed to the lower The animal reaches down to the vegetable and takes it up into itself The reverse is never the fact (Drummond) A transition of inorganic into organic, even by chemico electric operation, is not tenable The belladona test of death illustrates the argument A drop or two in the eye will dilate the pupil if vitality remains, no response is obtained if life be extinct Even if cerebral trauma vitiate a part of our test, eliminate that from the case and the point we make is established, the operative principle is alone in the vital force energies *Vis medicatrix naturæ* will express the true doctrine of therapeutics A handful of seeds were found in an Egyptian mummy hand, transferred into suitable soil they produced a beautiful plant Vital force in the seed required conditions not found in the dead hand, but supplied by contact relation with the soil. So the drug in the living eye is inoperative in itself, yet its presence and contact with the living tissues supplied the condition on which sensation arises, sensation being a life function, dilation ensues, and since sensation is a life function only and not a mind function, dilation is involuntary (Dunham) There is truly a place for drugs Therapeutics may as truly use medicine as vegetables use mineral, and in the same general way, the operative forces initiating from the higher Dr Musser is mainly right when he says "I thoroughly believe in drugs, I am sure I have seen an effect produced" The difference is merely in the standpoint of the operative forces involved, but a vital difference, for all the "vicious therapeutics" (Dunham) of modern practice arise from this error

This "New Interpretation of Operative Principles," a part only of which is touched upon, is the outcome of that unrest and dissatisfaction so long felt Glimpses of this true science were dimly and hazily, yet nevertheless really, seen by one and another in the centuries past Probably Sydenham, certainly Stahl, whose "Mysticism" contained the idea of the "anima" as the cause of both disease and cure, had more than a glimpse His teaching (supposed to be a hybrid, having as parentage the physiology of Descartes and the psychology of Van Helmont) that the "anima" or "force" forms the body, directs in all its functions and, mayhap, by negligence or want of wisely directed effort originates disease, which it at once attempts to cure by the activities and functions of its various parts, when modernized a little further, will find a place in the science now building on 'The New Interpretation of Operative Principles" Blumenbach was not far out in his reckoning when he esteemed Stahl as one of the most profoundly wise physicians the world had ever seen The men who half a century ago talked of "vitality," which when once "expended can never be regained," who proposed by therapeutic effort to "correct nature or help nature," and oftener it may be "let nature alone" were wiser than their generation Yet it was reserved for today for the clearer and fuller discovery of these central principles "Vitality is a distinct force and every pathologic change is consequent upon vital action," was a profound thought, prophetic of consequences in the near future, which Dr Lionel S Beal of London launched forth at an opportune moment two years ago Von Virchow, a year later, seeking in the mazes for "the point at which medicine begins to form a part of biology" and devoting the last days of his life to "establish and spread the idea that pathology should be considered a branch of biology", the American editor who, later yet affirmed, "there is no drug yet discovered, unless it be alcohol, which adds to the forces of the body," were pioneers in the field where Dr Dunham realized his "find" And now, in place of the unsolved problem of vital force, in place of confusion as to the nature and limitations of operative principles, with all the theories and hypotheses ingeniously contrived to make a whole of three halves, we shall have the rational and completed twentieth century science of medicine

Cuvier's teaching that "the first question in science is always a question of method," when accepted, revolutionized the previous systems of natural history, at least the classifications, and installed the method of investigation and experiment in place of mere "long distance" observation So this change in the "interpretation of operative principles" will work as great a revolution in medical teaching and science The same line of thought which we have pursued in therapeutics will be found equally applicable to pathology, and will overthrow much of modern theory and speculation as to the causes of disease Not to pursue the theme further, we maintain that it is absolutely incontrovertible that the "new interpretation of operative principles" is correct Whether the science built up to harmonize with the new operative plan be complete or not remains to be seen And yet this does not fairly state the point, for the "new interpretation of operative principles" grows out of the science itself and is part and parcel of it

JOSEPH CLEMENTS, M D

1113 West Seventeenth Street

The Troops in Santiago

NEAR SANTIAGO, July 13, 1898
[Delayed in Transmission]

To the Editor —Since my last on the 2d inst , yellow fever with its usual attendant scare has made its appearance in the camp of our army, nor is it anything but as a natural sequence of the violation of both the laws of health and ordinary precaution

After notification to Spanish authorities that Santiago would be bombarded after twenty four hours the foreign consuls in the city asked permission to let non combatants and foreigners pass out General Shafter granted the request, which was perfectly proper and most humane, but the great and inexcusable mistake was to allow them to pass through and disseminate among our camps and to have them hauled in our commissary wagons to Siboney, some nine miles distant, where is located our general hospital and the point of debarkation of troops and the embarking of our sick and wounded There are two roads leading to the northwest and north of Santiago where refugees could have gone and our troops would have been safe from contagion

Now to slightly recapitulate, for in my last I mentioned the want and great need of proper army sanitation On landing, both at Baiquiri and Siboney, our soldiers were allowed to enter and dwell in abandoned shanties, for that is true of the so called houses At Siboney two of the houses were converted into hospitals for the reception of the wounded from the battle of La Guacima In one room were four cases of measles within six feet of the wounded No doors closed any of the openings in the house Soldiers were pushed rapidly along, advancing without sufficient food, as the commissary department was landing supplies very slowly indeed There was and is bitter complaint about the commissary department The sun was quite warm and the troops marching rapidly on scant food—frequently a few hard tacks and water their only sustenance for twenty four hours or more—were unable to carry their rolls, hence they threw them aside, the result is that many soldiers are sleeping in the open air and on the damp ground Hospital tents had been established by Dr Cooke two miles and a half west of San Juan Hill, where General Hawkins made his brave charge, but the conflict was so fierce that the tents were soon inadequate for the wounded, and as tents were still on board the ships, poor wounded soldiers were compelled to lie on the wet ground for days, when they were removed to Siboney to the general hospital Ambulance service was very good, but the supply of ambulances was too limited , the result was that one half the wounded were hauled from the temporary field hospital to the division hospital in commissary wagons, which caused great suffering As I dressed the wounded for two successive nights I speak from observation

The pits for feces were not dug for several days after the canvas was pitched, hence an unpleasant odor from every thicket The wounded were compelled to go from twelve to twenty four and in some cases thirty hours without sufficient food Their appeals for soup or something to eat when I would go among them can never be forgotten The attending surgeons did all in their power to relieve the distress, but they had not the supplies sufficient.

The fever cases, not yellow fever, but fever caused by hot sun, bad water, sleeping unprotected, and last but not least from scant food, are now in little shelter tents only a hundred feet from my tent The number of this class of cases is increasing rapidly At this writing there are over 200 cases Just across a little pathway there are eight more shelter tents and in these there are six cases of yellow fever and two cases of suspected fever with no precautions whatever to prevent contagion, for along this path soldiers all pass every few moments Just to the east and not 200 feet away, is where the pack mules and commissary wagons camp nightly, all on a level and open ground where the water is now standing from one inch to four inches deep , this water slowly drains along between and into the tents of the sick There are plenty of hills and mountain sides near where comfortable tents could be located No pest house has yet been established at this camp At Siboney one has been established for nearly a week Just south of the general hospital at Siboney and across the railroad track is a coral reef too high for the sea waves to wash over it This reef is the nocturnal privy, and is one extended mass of filth, and effort is made to prevent it, although two pits are near Despite all the bad hygienic conditions the wounded are improving more rapidly than under more favorable conditions at home Of the surgery and fevers will write in my next , will state however that perhaps up to date 200 cases of yellow fever is a large estimate With rare exceptions the cases are very mild

The scare is worse than the disease, and want of hygiene worse than all ORLANDO DUCKER, M D

Dr Scheppegrell's Book

NEW ORLEANS, Sept 6, 1898

To the Editor —On my return to the city, a few days ago, I noted the reference to my recently published work on "Electricity in the Diagnosis and Treatment of Diseases of the Nose, Throat and Ear," among the Book Notices in your issue of August 20

An author naturally expects various kinds of criticisms, but the writer in medical literature has reason to believe that his work will receive fair attention at the hands of the more important medical journals, and that the criticisms will be made by some one competent to judge of the merits or defects of his work

In the case of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, there is, according to my opinion, more than the usual relation between subscriber and editor This journal is the official organ, in fact the mouth piece, of the AMERICAN MEDICAL ASSOCIATION In other medical publications, if the reader objects to the methods of the periodical, he simply cancels his subscription , with the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, however, the journal is part of the organization, and cancellation of the subscription is practically a resignation of membership The editor, in fact, holds his office, not through the good will of the publisher, but by the vote of the members or their representatives When, therefore, an article is submitted for publication, or a work for criticism, it is entitled, not only to the courtesy of the editor to a subscriber, but also of an officer of an association to one of its members

In the case of my work, which was sent you, I will admit that it refers to a special part of medicine, namely, of the nose, throat and ear, to which a physician devoting his time to general medicine would scarcely be expected to make a fair criticism Not only is this the case, but it refers especially to *electricity* in this department, of which even a specialist in nose and throat diseases might hesitate to venture an opinion of its merits Under the circumstances, therefore, had the JOURNAL simply given the name and title of the work, this would have answered the purpose, and it would not at least have given an erroneous impression On the other hand there are many men in Chicago who would have been able to criticise this work with credit to themselves and with justice to the author

In your criticism, the only part that refers to the work is the first paragraph "The illustrations in this book are fair, and the printing is well done The book is printed on good paper " This is as much to the point as if an artist had submitted a painting and the critic had reported that the was fair, the paint well prepared and

The other paragraph [illegible] refers [illegible]
It is simply a sarc[illegible]

any work on electro therapeutics, and which belongs to a method now out of date The reader expects not generalities, but a weighing of the good and bad points of the work which a journal undertakes to criticise

Not only is the criticism vague, but it is limited to the subject of electro therapeutics, which forms but a minor part of the work Had the critic, instead of limiting his attention to the "illustrations, printing and paper," read the work, or at least looked over the table of contents, he would have convinced himself that electro therapeutics forms but a small part of the work, a large proportion refers to the subject of electro physics, which has been reduced to as scientific a basis as any other department of physics The subject of electric illumination and transillumination is no longer one of controversy, but is now almost universally advocated Electrolysis, cataphoresis and massage, by means of electric appliances, belong more to electro surgery than to electro therapeutics, and the subject of the X rays has passed beyond its experimental stage, and is now admitted as a useful procedure in hospitals and medical colleges

The book has only recently been published, and I have thus far seen but three criticisms in addition to a number of simple notices Of the three criticisms referred to, one is in your journal, August 20, the second is in the *Journal of Eye, Ear and Throat Diseases*, Baltimore, July, 1898, and the third in the *Memphis Medical Monthly*, September, 1898 I herewith enclose a copy of the second and third criticisms, which bear on their face the evidence of a careful reading of the matter and a weighing of its merits They form a strong contrast with the vapid generalities in the official organ of the AMERICAN MEDICAL ASSOCIATION Yours very truly,

(Dictated) W SCHEPPEGRELL, M D

[Enclosures Extract from *Journal of Eye, Ear and Throat Diseases*, July, 1898 Extract from *Memphis Medical Monthly*, September, 1898]

ANSWER —This journal has not space to do more than give brief "notices" It rarely prints "reviews" The aim is to inform the reader what the contents are In this case the title was sufficiently explicit The manner in which the publisher performs his part of the book making is not a matter of indifference, but a proper subject of praise or censure Nothing was said to the detriment of Dr Scheppegrell's excellent work in our notice, which is now given the additional notice its author desires

Hospital at Fort Myer

U S GENERAL HOSPITAL, FORT MYER, VA
Aug 30, 1898

To the Editor —We have here a magnificent hospital under the command of Major and Surgeon W B Davis, U S A, whose earnest work is making this one of the finest hospitals in the country

We have about four hundred patients, and one ward containing 200 beds as yet not entirely filled This ward I believe to be the largest in the world

Most of our patients are typhoid, and every material is at the hands of the surgeon in charge with which to do his work

The charges and criticism relative to improper food and attendance is, in the case of this hospital, a falsehood, and I believe it to be so in the others, for as rapidly as possible everything is being accomplished for our sick soldiers

Respectfully, D H LAMB,
Acting Assistant Surgeon, U S A, formerly of Owosso, Mich

Is there Danger in Employment of Female Assistants by Dental Surgeons?

LA PORTE, IND, Sept 12 1898

To the Editor —Should dental surgeons employ female assistants? It would seem not if the following cases can be proven to be more than a coincidence Some years ago a dentist in our city had a young woman in his employ to assist in his surgical operations After remaining in the office several years she was married, and in due time an infant appeared upon the scene with a hare lip and cleft palate The young woman who next assumed her duties in the office remained eight years, when she became a wife, and recently gave birth to a daughter with the same horrid deformity I would like to hear from the profession if similar cases are on record

E L ANNIS, M D

PUBLIC HEALTH

Governor Tanner has appointed Dr A C Corr, of Carlinville, to the vacancy in the Illinois Board of Health He was last year President of the Illinois State Medical Society, and it is understood that he will be the next President of the Board

How to Use Millions Usefully Against Tuberculosis —The editor of the *London Practitioner* reminds his readers that some years ago a millionaire, burdened beyond most of his kind with a sense of the duties of his position and fortune, asked through a newspaper for suggestions as to the employment of his wealth in the way likely to be most beneficial to the public. For some reason or other nothing came of it If such a question were asked again, I should unhesitatingly answer that there could be no better object than the foundation of properly equipped sanatoria in this country for poor sufferers from phthisis That the public, if appealed to in the right way, would help liberally is not to be doubted The manner in which they support consumption hospitals shows that their help might be counted upon in an active crusade against the disease But the question is not one of merely philanthropic interest, it is of national importance, as it closely concerns the maintenance of the vigor of the race On this ground the co-operation of the State might well be asked In this country it is notoriously difficult to get even enlightened statesmen to attend to anything out of which party capital can not be made But even here the day is surely, if somewhat slowly, coming when ordinary legislators will be brought to recognize that the public health is the first and greatest of political questions Let us, in short, have a national crusade against a national disease

The Plague in India —It is discouraging to learn, as we do by telegraph, that after all that has been done for Bombay in the way both of curative and of preventive measures, the plague has broken out afresh in that unhappy city As yet, it is true, there is nothing alarming in the reports that have reached this country, for these speak of an increase of mortality from this source of only about 20 per cent, as compared with the figures for the corresponding weeks of last year But the distressing thing is that there should have been an increase at all, when we might so reasonably have looked for a decrease, if not even for an entire stamping out of the germs of this disease For the most recent advances in the science of bacteriology have been brought to bear by some of the most skilled European experts, on the vital problem presented by the condition of Bombay All the tried and prophylactic measures have been put into force there and the whole power of the government has been placed at the disposal of the health officers, who have been doing such valiant battle with their insidious foe, but the results show that when it has once found a congenial environment the expelling of it is very far from being an easy task Some parts of the city, it is said, have been so completely changed by the clearing away of plague infected dwellings that it would be difficult for an old residenter, in paying the place a visit after an absence of a year or two, to recognize localities with which he was, until recently, most familiarly acquainted It is to be hoped that the monsoon now prevailing will effect a cleansing both of the air and of the soil, and in any case the good fight must continue to go on It is all the more distressing to learn of this recrudescence of the disease when the reports tell that it has spread in rather a serious form to Southern India, and that in Madras the situation is complicated by an outbreak of cholera —*Sanitary Record*, Sept 5, 1898

The Plague in Central Africa —Hitherto three of the homes of Asiatic plague have been recognized, two of them in Central Asia, and the third in Southern Arabia Now, according to a correspondent of the *Medical News*, the range has been extended, for while in German East Africa, Koch found that a fourth focus of plague, a locality in which, according to the natives and missionaries, the disease has been endemic for as long as there is any tradition exists on the northern shores of Lake Victoria Nyanza in Uganda His attention was called to the fact by the recurrence in Kisiba, the most northwesterly district of German East Africa of certain suspicious cases At his request an army medical man investigated the disease directly in the infected district, and sent the specimens of a number of cases to Koch on the coast, three month's journey away The specimens were in excellent condition when they arrived, and Koch came to the absolute conclusion that genuine plague was endemic at least in this part of Central Africa From here he thinks that certain epidemics have gone down the Valley of the Nile and so invaded Europe The otherwise inexplicable epidemic of the disease at Tripoli in the seventies probably had its origin in some such way as this This plague spot is, in the progress of civilization, gradually becoming less segregated as it was Caravans often come from this district, and the English in British East Africa are engaged in building a railroad from the coast into this Victoria Nyanza district of Uganda, which will be completed in two years, and will still further add to the danger of the importation of the disease into Europe

Disinfection of Sputum —It is a serious wrong to allow the sputum of any consumptive to go undisinfected or undestroyed Destruction by fire should be the rule as far as practicable Comparatively few chemic disinfectants can be trusted to destroy the bacillus of tuberculosis in fresh sputum An abundance of experimental work has established this fact Solutions of corrosive sublimate are wholly unsuitable Milk of lime, a valuable disinfectant for some purposes, is too slow and uncertain for the disinfection of tuberculous sputum Chlorid of lime is too irritating to be kept in the vicinity of the patient Ascoli states that solutions of formaldehyde are efficient disinfectants for fresh tuberculous sputum, but its action, somewhat like that of corrosive sublimate in coagulating albuminous matter, dictates the advisability of awaiting a wider research in this direction Among the agents which may be trusted in this particular line of disinfection, the experiments of Shill and Fischer, Jaeger and others show that the phenol preparations, carbolic acid, lysol and solutol, have a special activity when applied to the destruction of the tubercle bacillus Of these, the work of Buttersack for the Imperial Board of Health of Germany indicates that lysol is distinctly superior to carbolic acid in the disinfection of tuberculous sputum, and the statement of the same investigator is supported by that of most of those who have tested it, that solutol is a still more active disinfectant than lysol For the disinfection of tuberculous sputum in spittoons, a 5 per cent. solution of carbolic acid or a 4 per cent. solution of lysol or solutol may be used The disinfecting solution should act twenty four hours before the sputum is thrown out. When no other disinfectant is available, hot lye, made from wood ashes may be used or a tablespoonful or so of washing soda may be thrown in and the vessel may then be refilled with boiling water covered and set aside to cool The same rules should be applied to the disinfection of sputum in pneumonia, influenza, and their application in chronic bronchitis is also desirable, for the reason that a tuberculuar cause remains long unrecognized in some of these cases —*The Sanitary Inspector*

The Scarification in Vaccination —The New York City Board of Health, having had occasion to revise its circular on information as to vaccin and vaccination, has dealt with the subject of the latter operation in the following terms "The part of the body to be preferred for the vaccination is at the insertion of the deltoid of either arm When the leg is vaccinated (possibly on account of the greater difficulty of keeping it quiet and clean) inflammatory complications are more frequently present and are apt to be more severe The skin at the place chosen should be made clean It is doubtful if attempts at more than simple cleanliness are of value, reports of series of cases in which one arm has been vaccinated with only ordinary attention to cleanliness and the other arm vaccinated after most rigid antiseptic measures had been carried out, indicate that no greater freedom from inflammatory complications resulted in the antiseptic arm than in the other The scarification should be made with a sterile instrument The Department of Health recommends the use of an ordinary cambric needle, because a new one may be used for each case and there is thus no possibility of the transference of an infection from one person to another When, however, the necessary precautions can be taken to render the instrument aseptic, any other sharp instrument serves as well It is of great importance that the scarified area should be not more than one eighth of an inch square, because the larger the area the greater the tendency to subsequent infection and to inflammatory complications Moreover, with the more concentrated virus at present issued by the Department of Health, a small scarification is ample for invariable success It should be noted that a vaccin vesicle enlarges peripherally, and the resulting crust always covers a considerably greater area than that originally scarified The virus should be rubbed in thoroughly and allowed to dry for at least ten minutes It is a convenience to blow the virus from the capillary tube in which it is contained on to the accompanying piece of wood and then rub the wood on the scarified area, instead of blowing the virus directly upon that area

Increasing Demands for the Sanitation of Creameries —This subject is a theme of a paper in *Public Health*, July, by Dr Lippincott of Hopkinsville, Pa , who is himself a veterinarian and a dairyman "As is customary, at such establishments, the wagoner brought the milk can filled with "slop" that is supposed to be good enough for hog feed It is generally understood on the outside that the farmer who sends his milk to the creamery gets skim milk in return, but when it comes to reality, they are only entitled to the slop out of the out wells where all refuse of the creamery is conducted This is exposed to all kinds of weather, but nothing affects these wells as does the sun and hot weather They are never cleaned out and having run into them each day skim milk, water, dirt and washings from the buildings and utensils, this mixture came home in our milk cans Imagine my surprise when the man emptied the return cans of slop, which had the foulest odor not unlike the very worst kind of a water closet or human excreta After a few returns of this kind my man refused to wash the cans, and no one could blame him *If I could present a sample to this meeting your noses would suggest that one dose would suffice* Yet the farmer continues to cart this home, and his swine are forced to drink it or starve This is not only true of our creamery, but all over the State In our experience, after washing and rewashing the cans retained the filthy odor two or three days yet the farmers fill these same cans in the evening with fresh milk for the next trip this is repeated daily, from this milk comes the butter to your table and mine I am informed that the State Board of Health is unable to remedy this evil for lack of legislation New Jersey is fully prepared to meet and correct any such matters Imagine my surprise upon receiving from Dr Lee, the secretary of the State Board of Health, a reply to my suggestion that an inspector be sent, that this great Commonwealth has no such inspector If Dr Pitfield is looking for a fertile soil for bacteria, a visit to one of these blind wells on a hot day would show him all he needs I engaged the attention of the proprietor, pointing out the facts and the easy means of correction, but I am met by the remark it is time enough when such becomes a aw They can easily be kept clean at little expense by having an outlet making such a flush well in a place of a stagnant pool "

Preventive Measures Against Tuberculosis at New York City —Dr Herman M Briggs gives in the *London Practitioner*, June, the latest account of the results in New York consequent upon health board measures for the restriction of pulmonary phthisis He divides the efforts of the Department of Health under the three heads of notification, education and other preventive measures While still far from complete, especially among that class under the care of private physicians, the notification of cases of tuberculosis shows a marked and continuous increase Thus, during 1894, the year in which registration was begun, 278 cases were reported by physicians and 3985 by institutions, while in 1897 1919 cases were reported by physicians and 7653 cases by institutions—9572 cases altogether Another evidence of increasing confidence on the part of the profession in the attitude of the Department of Health with regard to the control of this disease is afforded by the increase in the number of specimens of sputum sent in for examination, each specimen which contains tubercle bacilli representing, as it does, a report of a case These specimens have increased from 511 in 1894 to 2703 in 1897, while during the four years since the work was begun, a total of 6897 specimens has been examined The educational influence and value of the measures adopted by the Department have been marked The inspectors report a most gratifying increase of intelligence among the better class of the tenement house population with regard to the true nature of the disease and the usual method of its transmission to others They find in many instances on their first visits to consumptives that efficient means have been taken to properly care for the sputum, through the use of rags (which are afterward burned) in place of handkerchiefs, or of cups containing water or some disinfectant, etc Another evidence of the increase of popular intelligence is found in the requests from citizens, now received by the Department almost daily, for the disinfection of infected clothing, etc, and for the inspection of premises occupied by consumptives Where the premises occupied by consumptives are vacated by death or removal and are, in the judgment of the inspectors, probably infected, recommendations for their renovation are made to the Board of Health, and on the basis of the recommendations, orders are issued by the Department on the owners of the premises, requiring such renovation It will be observed that *renovation* —not disinfection—is required This involves the application of simple, and in tenement houses, inexpensive measures, i e, scrubbing painted woodwork and floors with a hot soda solution and repainting, repapering or rekalsomining the walls These measures are certainly efficient in ridding an apartment of tubercular infection (while efficient disinfection in such apartments is difficult or impossible), and at the same time they are easily understood, leave the premises in an improved condition, and as a consequence are cheerfully acquiesced in by the tenants, and are promptly carried out in almost every instance by the owners of the buildings Where the consent of the owners can be obtained (and there is but little difficulty in this), infected bedding, clothing, carpets, etc., are removed by the Department, on the recommendation of the inspectors, to the disinfecting station and disinfected by steam or destroyed at the option of the owner, without expense to him

Bubonic Plague Spreading —Advices from Simla, dated August 29, announce that there were 2300 deaths last week in the Bombay Presidency The epidemic is spreading and there has been a fresh outbreak in the Province of Hyderabad

Consumption Among the Negroes —Dr James Evans of Florence, S C, writes that the susceptibility of the colored race to phthisis, and its extreme fatality among them, has made a deep impression on every observant physician in the South, and the subject is invested with peculiar interest as the excessive mortality has overtaken the race since emancipation, showing that the disease is more prevalent now than it was during the period of slavery In investigating this phase of the subject several years ago, I made inquiries among the rice planters dwelling on the coast, who were the owners of a much larger number of slaves than elsewhere in South Carolina, as to the frequency and mortality of consumption among their slaves The result of this inquiry was that phthisis in any of its forms was an exceedingly rare affection among negroes on the plantations Many of these planters had no recollection of seeing a plantation slave affected with the disease, and it was even seldom seen in those who visited in the towns and cities where they were more exposed to the infection The negro engaged in the cultivation of rice is employed for a large part of his time during the winter months in repairing the dykes and cleaning and digging ditches, and the consequent exposure in the performance of this work often gives rise to the acute forms of pneumonia and bronchitis Yet they were singularly exempt from consumption The slave represented so much invested capital, and was warmly clad, well fed, comfortably housed, and when sick had the best medical attention Consequently the mortality among them did not exceed that of white men The death rate in Charleston in 1860, of the negro, was exactly that of the white man, 12 per 1000 In 1895 it was 29 10 colored, 18 70 white, per 1000 A comparison of the phthisis death rate in the city of Charleston among whites and colored in decimal periods from 1865 to 1895 inclusive, reveals some startling facts The deaths from consumption, in the period from 1865 to 1895, were as follows In 1865, whites, 26, colored, 74, in 1875, whites, 54, colored, 132, in 1885, whites, 57, colored, 209, in 1895, whites, 39, colored, 194 Total deaths in 31 years—whites, 1525, colored, 4975 Estimated population in 1895 whites, 28,870, colored, 36,295 The police regulations in force on most plantations did not permit the slaves to visit adjoining places without a permit, and they usually retired early at night and arose at an early hour next morning As soon as emancipation occurred, there was an exodus of the negroes from the rural districts to the small towns and cities, where they congregated in large numbers, and there was overcrowding in every place that could afford the least shelter And even now, on farms remote from the towns, they evince the same tendency of overcrowding their little cabins with more people than they can possibly accommodate with comfort or safety There is no disease which claims as many victims among the negroes as consumption And the prime cause of this excessive mortality is room density, too many living in the same room —*Bulletin of the Ohio State Board of Health*, June

NECROLOGY

Thomas Sexton Robertson, M D, University of Vermont, 1879, of New York City, died at his home September 7, aged 44 years Born in Glasgow, Scotland, he took a medical course in London, and after graduation in this country, began practice in New York as a specialist in nervous and mental diseases

W S McNairy, M D, a graduate of medicine of the University of Pennsylvania, died in his 82d year in Washington, D C, September 3 He was forty six years a government clerk in the U S Naval Department, and continued at his desk until within a week of his death

John L Neilson, M D, Medical College of Ohio, 1866, died suddenly in Boston, Mass, September 1, in his 54th year He served twenty nine years in the Medical Corps of the U. S. Navy, was a member of its examining board and at the time of death was a medical inspector at the Charleston navy yard.

Major **George McCreary**, surgeon, United States Army, who died August 23 on the *Catania* en route from Santiago to Camp Wikoff, from dysentery, following yellow fever, and who was buried at sea, was a native of New York. He entered the army as an assistant surgeon, with the rank of captain, on Feb. 17, 1880. He reached the grade of surgeon with the rank of major last year and accompanied the army to Santiago de Cuba, where he rendered excellent service until he was stricken down with the disease which resulted in his death.

Levi J. Rice, M. D., of Hillsdale, Mich., August 31, aged 94.——Fred A. Harpold, M. D., of Lower Salem, Ohio, August 31.——L. K. Garfield, M. D., of Algona, Iowa, September 2, aged 78.——Franklin Burr, M. D., formerly of Buffalo, at Greeley, Colo., September 1.——C. J. Covey, M. D., of Grand Ledge, Mich., September 1, aged 73.——W. V. Camp, M. D., of Hoxie, Ark., August 30.——C. B. Carneth, M. D., of West Superior, Wis., September 2.——A. J. Coward, M. D., of Clinton, Tenn., September 7.——Robert Jordan, M. D., of Jordan Springs, Va. September 4, aged 75.

MISCELLANY

Habitual Luxation of Lower Radio Ulnar Articulation.—This produces much functional disturbance, which is often ascribed to every cause but the right one. Hoffa has treated three cases by fastening the two bones together with three deep sutures embracing the periosteum of each, thus affording a firm support to the head of the ulna. The functional results were perfect in less than three weeks.—*Cbl. f. Chir.*, July 2.

The Zambaco Prize.—Zambaco Pasha of Constantinople has endowed the French Société de Derm. et de Syph., with funds for a biennial prize of 900 francs, to be awarded first in 1900 for the best article in French on the Contagiousness of Syphilis at All Stages of the Disease. Communications must be sent in to the secretary, Dr. Hallopeau, Boulevard Malesherbes, 91, Paris, France, before November 30, 1899.

Nude Out of door Life in Therapeutics.—An editorial in the *Gazette Méd. de Paris* of August 13, describes a sanitarium at Veldes in Austria, in which the patients—mostly neurotic subjects—live in shelters open to the air and discard all clothing except a pair of bathing trunks and a straw hat. They dine and lounge on rugs spread on the green sward, after games and exercises that recall the South Sea Islanders. A physician is connected with the establishment, appointed by the Austrian Government, and no undue license is allowed. The sexes are treated in separate quarters. This retreat is reached from Innsprück in the Tyrol, via Toblach and Villach in the Oberkrain.

Paresthetic Meralgia.—The *Revista Méd. de Chile* for February, contains the observation of three cases that confirm Roth's recent description of this affection. After walking or fatiguing the legs even slightly, the external muscles are the seat of strange sensations of heat and cold, amounting to actual pain. Hairless patches are also to be distinguished in the region, with normal sensibility, "smooth as parchment" (Roth.) No benefit was derived from any treatment. According to Roth's experience diabetes or tabes invariably followed in the course of a few years. In the new cases there were diabetic or neurasthenic family antecedents and one case had an inextinguishable thirst that suggested diabetes.

Direct Bronchoscopy.—Prof. G. Killian of Freiburg announced at the recent South German Congress of Laryngology, that he has succeeded in visually inspecting the bronchi below the bifurcation. The bronchi, he finds, are much more flexible than usually supposed. After cocain anesthesia he introduces a stiff tube into the bronchus, which straightens it until he can inspect it with the eye and examine even into the branches. The subject does not find the experience particularly disagreeable. He sits erect, the head thrown back and to the left, while he breathes easily through the tube, the observer standing on the right. Killian has tested it until he has established its entire harmlessness. For a man he uses a tube 9 m. m. in diameter. Once past the throat, the tube slides down by its own weight.—*Munich Med. Woch.*, July 5.

Electric Treatment of Epithelial Cancers.—Fabre Domergue asserts that the orientation of the epithelial elements determines the character of the tissue; with a centrifugal orientation the elements develop with a continuous exfoliation of the horny layer and renewing of the rete mucosum, without any tendency to break through the basement membrane, while centripetal orientation is abnormal and leads to partial or total infiltration of the tissues below the basement membrane. He suggests that we utilize the property possessed by the electric current of turning certain unicellular organisms until their long axes parallel the direction of the current. Galeotti has also recently established that cellular division in the epidermic elements of the salamander is affected by the electric current. "It may be possible to restore the disorganized cells of epithelial cancers to their normal centrifugal orientation and arrest the growth of the neoplasm."—*Bull. de l'Acad. de Méd.*, June 28.

In Honor of Berzelius, the Swedish Savant.—A great memorial fête will be held in Stockholm, October 7 next, on the occasion of the fiftieth anniversary of the death of the savant Berzélius. Every scientific society in Europe will be represented, it is expected. In 1819 Berzélius was the guest of the City of Paris. He was an intimate of Laplace, Berthollet, Gay Lussac, Ampère, Arago, whom he visited in Arcueil when every Sunday they met and sat under the trees and discussed the scientific questions of the day. Three years later Berzélius was made a member of the Institut de France, but he found the ceremonious display there less amusing than the little gatherings at Arcueil, and he was seldom seen at the Institut. Berzélius, who was born in East Gothland, Sweden, in 1779, studied chemistry and medicine at the University of Upsal. His most important work is "Larebok i Kemien" ("System of Chemistry"), in three volumes, which has been translated into every European language. He was Professor of Medicine and Pharmacy at Stockholm from 1807 till 1832.—*N. Y. Times.*

Bones can be Introduced for Inspection of Experts.—In a malpractice case where negligence was charged in the treatment of a broken leg, causing gangrene to set in, and requiring an amputation of the leg, the court of appeals of Kentucky holds, Williams vs. Nally, that it was not improper to allow the bones of the fractured leg to be introduced for the inspection of the experts. It also maintains that the testimony of those not professing to be experts with respect to the actual condition of the leg was competent, because they spoke only of what they saw and knew, expressing no opinions. Nor does it think that it was improper to allow counsel for the plaintiff to incorporate into some of his questions quotations from medical works, as part of his questions, when catechising experts as to their technical knowledge. Finding no reversible error it affirms a judgment for $750, against the physician, who, by the way, was sent by a justice of the peace to attend the case under instructions to give his patient all necessary attention but not to run the county to unnecessary expense.

Estate Liable for Support of Lunatic.—The supreme court of Tennessee says in the case of McNairy County vs. McCoin, an action brought to recover payment for the board and maintenance of a lunatic admitted to a county asylum for the pre-that the duty imposed by the common law upon the guardian to maintain and support his ward is no less obligatory than that imposed upon the husband to support his wife, and if the guardian, with means of the ward at his disposal, breaches his duty, and permits his ward to become a charge upon the county, it should be reimbursed for expenses incurred in supplying necessaries to said ward It is true, the county asylum established under the laws of Tennessee is a charitable institution Still, it was designed for the care and maintenance of indigent paupers, and not for the benefit of those who have means sufficient to support themselves If, therefore, it appears that the county, through the neglect of the guardian, has been compelled to provide for one who was not a pauper, it would seem but just that the county should be indemnified out of the funds belonging to the ward, as the court holds, and to this effect, it says, is the great weight of authority, a contrary view of the supreme court of Indiana being pronounced out of line with the current of authority, and but the decision of a divided court

The Neuron Theory Tottering—Franz Nissl publishes in the *Munich Med Woch* of August 2, 9 and 16, an account of his recent investigations in regard to the nerve cell and gray matter He has established a number of important facts which undermine the neuron theory and demonstrate that the nerve tissue consists of nerve cells and a specific nervous substance, (the gray matter), a fibrillary substance, originating in the nerve cell protoplasm It evidently represents the highest stage of differentiation in the animal organism and is an especial functional factor in the mechanism of the nervous system, the functionating element, while the nerve cell is the forming and nutrient element from which the other is developed It is interesting to note in his cuts how this functionating element predominates in man—the higher the development of the mammal, the less nerve cells there are in corresponding perpendicular sections of the cortex Among the facts on which he bases these assertions are the discoveries of Apáthy and Bethe of a co ordinated reflex in an invertebrate (carcinus mænos), without any central nerve cell, also that this reflex rapidly subsides, having no continuing power Further, his and others' demonstration of fibrils in the unstainable portions of the cell body show that these primary fibrils undoubtedly constitute the conducting element Another fact is the classic lack of proportion between the alterations in the nerve cell after intoxication or other injury and the functional disturbances, the cell may return to a perfectly normal condition, while the function is still lost His own research has been principally in the line of the effect of various poisons on the nerve cell He finds that each poison affects the nerve cell of the cortex in a special, almost a specific, manner (except in case of very slow, gradual intoxication), and that the alterations produced are chemic or physical or both, and are primarily merely the expression of the disturbances produced by the toxin or other injury in the material equilibrium of the nerve cell

Heart Disease from the Standpoint of Life Insurance—Dr Robert H Babcock, *Medicine* Vol iv, p 177, *American Medico Surgical Bulletin*, in discussing the attitude of the companies toward their examiners as one of distrust regarding the liability of reports accurate enough for a basis of expectancy, says that tachycardia of 90 or 100 is often due to the perturbation of an examination, the use of tea, coffee or tobacco, and may hap the naturalness of some individuals A cardiac murmur is the least important, its intensity is no criterion of its gravity, on the other hand, a dangerous lesion may declare no murmur at all Robust men of large frame, ample chests, eaters of meat thrice daily, who take comparatively little out-door exercise, with the handicap of active mentality or great responsibilities, are the risks which die unexpectedly in the fifties or early sixties An examination of the heart in these cases may reveal an absolute dullness usually normal, while deep percussion may prove an increase of relative dullness sufficient to constitute cardiac enlargement Dwelling upon some of the conditions which should determine one's opinion of the likelihood of an applicant with a compensated mitral insufficiency or aortic stenosis living out his expectancy, the writer regards the tendency to recurring attacks of articular rheumatism, or a gonorrhea, or some other infectious disease present, and liable to set up fresh endocarditis as of unfavorable prognosis Age also influences the prognosis, as if the person be beyond middle age it is probably of sclerotic origin and progressive The occupation is of utmost importance, since, if it subject the individual to vicissitudes of weather, or to cardiac strain from undue exercise or physical tax, compensation is not likely to be long maintained

Obscure Sources of Poisoning—Dr Clement Dukes, physician to Rugby School, refers to two cases of the above nature The first of these was an adult male having the symptoms of plumbism The patient was a gardener, and the physician minutely searched every possible source of poisoning in his house without discovering the cause Failing in this, inquiry was made into his habits from rising to retiring, and the cause was traced to this he breakfasted early, went to work, and between 8 and 9 A M visited a certain ale house to have a glass of beer, where he was usually the first customer As the beer was drawn by the beer pump from the barrel in the cellar through a lead pipe he evidently imbibed with his, often probably hard, beer his daily dose of lead This visit was at once given up, he recovered from his poisoning, which has never recurred, and he now allows some one else to have the first glass A few weeks ago a young woman, who evidently had something on her mind and was suffering considerably, which apparently arose from morphism, called to consult Dr Dukes After considerable patient inquiry the following facts were elicited Some years since she had suffered from a painful rectal trouble for which morphia suppositories had been prescribed, which not only relieved her local pain but doubtless produced other general peaceful effects Feeling very wretched from too long a ride on her bicycle, which made her quite ill, she remembered her suppositories and resumed them, using several daily for a considerable time, with the result I have stated —London *Lancet*, April 2

County has no Right to Discharge Physician Without Cause—The first of several questions deemed important enough to be specially certified up to the supreme court of Texas, in the case of Galveston County vs Ducie, was as to whether the commissioners' court had authority to appoint a county physician, at a stated salary, to perform duties comprising the giving of medical attention to the prisoners at the jail, both the criminals and the pauper insane and county paupers at the poor farm and any one sick within the jurisdiction of the county, confined as a prisoner pauper, or lunatic, and to attend inquests whenever anybody was found dead The answer of the supreme court, handed down May 9, 1898, is that the commissioners' court of Galveston county was authorized to make the contract for medical services to be rendered to paupers and prisoners for whose care and support the county was required to provide, but that it had no authority to make the contract for the physician's services at inquests, and that to that extent the contract made was not binding upon the county The explanation of this is that counties are not liable for the services of medical men at inquests which may be held under the provisions of the Texas Code of Criminal Procedure Yet, as already suggested, the court holds that, although the stipulation in the contract for the physician's services at inquests was ultra vires, or beyond the power of the commissioners' court to contract, it did not render the agreement invalid for that part which the county had the power to con tract for. And it insists that, so far as the commissioners' court had authority to make the contract referred to, the county was bound to the same extent an individual would have been, and it had no right to discharge the physician without cause. If wrongfully discharged, he would be entitled to recover the amount contracted to be paid him, less so much as attendance upon all inquests in the county would be reasonably worth, and less any additional sum the evidence might show that he could make in the practice of his profession by being relieved of attending to the county cases. But the contract in question, not contemplating that the services to be rendered for the county would occupy all of the physician's time, but that he might give what spare time he had to private practice, the court holds that, when wrongfully discharged he would not be obliged to seek other employment, to reduce the damages against the county, because that would not be consistent with his regular business, some weight also being attached to the fact that it did not appear that there was any other business of like character in which he could have obtained employment.

Practice of Medicine by Clergymen.—The *Lancet* states that the Roman Catholic bishop of Augsburg has recently made a communication to the clergymen of his diocese on the subject of the increasing tendency of the clergy to give advice in cases requiring medical treatment, a practice which he condemns as being at variance with the ordinances of the church, and he charges his clergy to avoid anything which may have the appearance of interfering with the work of the medical profession. This order is the more remarkable because Woerishoffen, where the late Father Kneipp lived and his successors still continue his work, is in this diocese. The expression of similar views by other clerical dignitaries would no doubt have a beneficial influence as tending to prevent misunderstandings between the two professions. That quackery has its most fervent adherents among the upper classes was clearly shown by a recent occurrence. One of the leading newspapers of Berlin published a letter written by a medical man showing that a so called "magnetopath" had pretended to cure patients by means of magnetic fluid coming from a well known Berlin medium now resident in America. This medium had formerly caused a certain amount of sensation in connection with spiritualist meetings, but eventually left the city when it was shown by some medical men that she had been carrying on a system of imposture. A few days after the insertion of this letter a public declaration appeared in the advertising columns of the leading Berlin journals, signed by a great number of patients of the quack. The signatures were for the most part those of members of the nobility and of the upper classes, who solemnly stated that they had been cured by this man after having been attended without success by legally qualified medical practitioners. The great popularity of every kind of quack treatment among the upper classes leaves little ground for hope that unqualified practice will be made illegal.

Leprosy in Hawaii.—A pamphlet on this subject has been published by Dr. Ashburton Thompson. He quite fully considers the question of imported labor from leprosy areas, but finds little evidence in support of the theory that the disease was introduced in that way. The first reliable observations on the occurrence of leprosy in Hawaii were made between 1855 and 1863, but the rate of its diffusion is very uncertain. Dr. Thompson remarks: "All competent witnesses hold the following opinion—that there is no record or distinct tradition of the invasion of the disease. When attention was first attracted to it cases existed in every island of the group; it is not known or suggested either that any island was attacked before the rest, or that any remained free after the rest were known to suffer." It is thought at the present date by those at Honolulu, who are in the best position to judge, that the outbreak is now declining. The evidence that this is so is not as yet such as can be easily apprehended by the foreign visitor, and it is the case that during the last thirty years a similar opinion has been expressed, from time to time, only to be contradicted a little later by acknowledged facts. Great difficulties have been experienced in carrying out a policy of isolation. In 1865 the necessary land was acquired, which thenceforward become known as the Settlement, but for many years constant communication was carried on between the lepers and their friends on the other islands. Consequently, the author says, no account of the fluctuations of this endemic can be written; all that can be furnished is a statement of the number of persons annually removed to the Settlement, and this is given for the term of years from 1866 to 1895, in a table. But these numbers stand in no known relation to the total affected in the whole group, and fluctuate largely, if not exclusively, in correspondence with terms of greater or less executive energy, and are hence of little scientific value. In fact, as Dr. Thompson himself observes, the value to etiology of the present case must be classed scientifically as "unobserved," as no records were kept of the original inhabitants of the islands who became lepers, but the vast majority of cases were observed in those families whose ancestors had been imported into the islands.

An Emergency Call Requited by Prosecution and Fine.—Dr. Leichtentritt, a practitioner of Berlin, has had a very disagreeable personal experience, the details of which he has published in the *Aerztliche Sachverstandigen Zeitung* for the benefit of his professional brethren. Dr. Leichtentritt when on his way home and near his residence, one evening, was asked by a policeman to see a woman who was giving birth to a child, in a water closet. He did so, and found that the woman had just been delivered of a girl, the placenta being still in the uterus. A crowd of women was present to watch the proceedings and to give advice to the patient. The surroundings not being the most suitable for obstetric manipulations, Dr. Leichtentritt only tied the umbilical cord and ordered that the woman, whose name and address he did not ask for, should be conveyed by the policeman to the nearest hospital for the removal of the placenta. He then went away, feeling inwardly content with the charitable act which he had performed under such strange conditions. Some weeks afterward the woman called on him to ask whether he had notified the birth of the child to the registrar. She told him that she wished the child to be baptized, and according to law it was necessary for the clergymen to see the certificate of the registration of birth. Dr. Leichtentritt said that he had not notified the birth and explained to the woman that it was the duty of the hospital officials to do so. Not long afterward he was officially summoned before the registrar, who drew up a long report of the case, and his troubles were supposed to be at an end, but to his great disappointment he received an order from the magistrate to pay a fine for infringement of the registration laws. Dr. Leichtentritt refused to pay, not feeling that he had committed any offence, and rightly believing that he did not deserve to be fined for help freely given to a poor woman. Legal proceedings were taken against him, but judgment was given in his favor on the singular ground that he had not been "present" at the delivery, as the child was already born when he arrived on the scene. The law is to the effect that medical men or midwives or other people "present" at the birth of a child are bound to notify the birth to the registrar, but it was not applicable to the present case. In future Dr. Leichtentritt and some other medical men will probably be less ready to respond to appeals for their assistance.

The Profession and the Interviewer.—The *Scalpel* reprobates the action of certain practitioners in supplying the press with bulletins and interviews regarding the sickness of the great and as an example instances the fact that day by day the press described the progress of Mr Gladstone's illness, day by day with ghoul like eagerness the press detailed the varying phases of his malady, and Mr Gladstone literally was killed by inches What useful purpose could be served by such details?—save the selling of a few extra copies, and the making of a few extra half pennies Still worse, in our opinion, are the reported interviews as to the exact nature and progress of the patient's illness, how he consulted Dr So and So, how he actually saw Dr Carter of Liverpool, how he then went under care of Dr Blank and Dr Blank If such interviews and such actions are sanctioned in high places, why should not Dr Minimus give the reporter details of the illness of the local great man and advertise himself There is only a difference in degree In each locality the big man of the place is as important to the place as Gladstone was to the larger circle Bulletins are, however, condemned in the case of the smaller man But the question resolves itself into a small compass It is not a question of the high or low position of the patient The medical attendant is consulted in a confidential capacity, he has no right to let the public into his confidence He should say to all reporters and interviews—"I have told the relatives my opinion of the case, if you want any information you must go to the relatives I can not enter into details which I obtained in my professional capacity." We have seen in some of our illustrated journals ghastly pictures of the death chamber of Mr Gladstone The Ex Premier is almost at his end, his wife holds his hand and his family are round his bed This picture has no merit from an artistic point of view, and it certainly appears to us to be in the worst possible taste The inner life of our great men may sometimes be legitimately peered into, but certainly their death chambers should not be invaded—a veil should be hung over this last solemn act We trust that the College of Surgeons and Physicans or some other official body will in some way express an opinion in general terms upon the proper attitude of medical men when attending distinguished patients

Prior Removal of Ovaries Ground for Annulling Marriage —The exceedingly novel and important question was raised in the case of Wendel vs Wendel, whether the husband is entitled to the annulment of a marriage contracted without knowledge on his part that his wife was physically incapable of conception as the result of a surgical operation, such as the removal of her ovaries, known to her, but concealed from him Section 1743 of the New York code of civil procedure provides that an action may be maintained to procure a judgment declaring a marriage contract void, and annulling the marriage, among other causes existing at the time of marriage, where one of the parties was physically incapable of entering into the marriage state In deciding the question presented, under this provision, Mr Justice Hirschberg of the special term of the supreme court of New York, Kings County, follows, in part, this line of reasoning Was the defendant wife, at the time of the marriage, physically incapable of entering into the marriage state, within the meaning of this statute? The answer depends in great measure upon what are recognized by law as the objects and purposes of marriage If sexual intercourse alone is so recognized, then it must be conceded that the defendant in this case was physically capable But the creation of a family is also regarded as one of the chief purposes of a matrimonial union, and it is difficult to see how an individual can be physically capable of performing the contract who has lost the organs essential to conception The question is different from that presented by sterility or barrenness It is well settled that a marriage will not be annulled for the mere barrenness of the wife Not only is such a condition and its continuance difficult, if not impossible, to prove, but its existence, if established, may not be innate, but only peculiar to an inharmonious combination In such cases, whether the power to conceive or to impregnate be at issue, the question of the condition and its permanence rests on hypothesis and speculation, and is practically beyond the pale of judicial scrutiny Impotence in such cases is the sole and settled ground of nullity Continuing, the judge says that it seems to him that the question is vitally distinct where the barrenness is absolute, is not a constitutional quality or a functional failure, but a physical incapacity, resulting from congenital malformation or the total loss of the organs of conception by disease or the surgeon's knife So he holds, December, 1897, that a person destitute of child bearing organs is physically incapable of the chief and higher purpose of matrimony, and consequently of entering the marriage state And it follows, he holds, that in concealing from the husband the fact and extent of her misfortune, the defendant in this case procured his consent to marry her by fraud, which constituted a good ground for divorce But had the plaintiff married her with knowledge that the surgical operation performed on her involved the removal of her ovaries he would, of course, be estopped from action because of her physical condition The fact that in this case the prospective husband had asked whether she was physically and mentally capable of being a wife, and that the judge says that good faith required that she should have then disclosed the fact that the surgical operation involved the removal of the ovaries, perhaps casts some doubt on whether the judge would have decided as to the fraud and divorce therefor, as he did, though his reasoning set forth would seem to have required it, had not the inquiry been made of her

San Francisco

Now that the war is so nearly over, and that the proper thing to do is to seek for "who is to blame," it would perhaps not be be amiss if some inquiry were set on foot in the effort to establish the blame for the many instances of alleged mismanagement in the camps in and about San Francisco When the volunteer regiments gathered at this point a few of the companies were camped at the Government Post called the Presidio, but afterward most of these and all subsequent arrivals were encamped on the other side of the city, in some sand lots which have heretofore been given up to the trade wind and the fog Of sewer facilities there were none, and of water there was a very meager supply in this new location, called Camp Merritt On account of the cold winds and the heavy fogs almost constantly prevailing, that section of the city had been but little built up Here the men were camped and here they built their privies, just about *fifty feet from* the camp kitchens, at the end of a month the stench from the combination of kitchen and privy was painfully evident to passengers on the cars which pass that side of the camp and perhaps a hundred feet from the camp limits Who permitted the locating of the privies so near to the camp kitchens? And who indeed, was responsible for locating the camp in these wind swept and foggy sand lots, where water is scarce and sewers there are none? Who supplied musty straw for the bedding, with the result that there was an epidemic of otitis media from micro organisms infecting the straw, which resulted in several deaths from mastoid disease and meningitis? Who is responsible for supplying the zoölogic collections called bacon, which sometimes have been issued to them for rations? These and a few more questions might well be asked, in view of the very high death rate and the large sick list It was rumored that the Southern Pacific, which corporation controls all the street car lines running out to Camp Merrit, was largely instrumental in having the camp located in the sand lots, for it has no car lines running to the Presidio, and its rivals have no lines giving service in the vicinity of Camp Merrit This rumor was denied, but that is but what one could expect, and in view of the weight which political pull and corporation influence seems to have, the denial means nothing At present there are about three hundred and fifty men on the sick list among the troops which were recently removed to the Presidio from Camp Merrit, and the death rate is not what one could conscientiously call small When investigations are being urged with greater emphasis from day to day, why not look into some of these things which, in view of the results, may be called outrageous blunders?

IT IS STATED, on good authority, that the joint committee of the Board of Regents and the Faculty of the Medical Department of the University of the State of California have in contemplation a plan for making the medical department one of the leading medical schools of the country They have entered into correspondence with Johns Hopkins, to ascertain the data of the plan of operating that famous school, and the necessary expense of conducting a school on very similar lines Certainly the plans as outlined by a member of the joint committee will, if carried out, put the medical department of the university in a place second to none in this country A medical library that will be a library in the fullest sense of the word, is already decided upon and will have been commenced by the time the new buildings are in use Through the instrumentality of Dr Philip King Brown and the generosity of the widow of the late Dr Richard John Hall, almost the entire library collected by Dr Hall is to be given to the university for the use of and to be placed in the building of the medical department This library includes a large number of complete files of medical journals American, English French and German, and is of considerable value Other notable accessions are in view and it is to be anticipated that before the first of the coming year there will be at least five thousand volumes in the library A large and excellently adapted room has been set aside for this purpose and the shelving is now being made

Philadelphia

Six Hundred Soldiers lie ill in the hospitals of Philadelphia And yet this large number of sick represent but a proportion of the total number now being treated elsewhere

Philadelphia Mortality Report —The number of deaths for the week ending at noon, September 10, was 537 an increase of 124 over the previous week, and of 148 over the corresponding period of last year Of the total number 172 were in children under the age of 5 years, cholera infantum being very prevalent owing to the excessive he The principal causes of death were Apoplexy 18, dysentery cancer 16, diarrhea 3, inanition 10, cholera infantum 50, marasmus 25, consumption 57, old age 25, heart disease 41, suicide 8, uremia 15 Infectious diseases Diphtheria 64 cases, 10 deaths, scarlet fever 12 cases, 1 death, typhoid fever 222 cases, 28 deaths Total 298 cases, 39 deaths, a decrease of 47 cases and 14 deaths from preceding week

September Has Been Hot in Philadelphia —Physicians who have remained in the city during the summer will not forget the past few months for years to come While the weather man stated some time ago *that it had been the hottest for* thirty years, it was a source of much pleasure to feel that the hottest was over after the first of September had been passed But on the 5th inst a temperature of 91 was reached with the humidity at 83 per cent ending in 6, deaths and 20 prostrations On the 6th there were 6 deaths and 18 prostrations On the 7th 4 deaths occurred Since August 31 there have been 41 deaths attributed to the intense heat

Quarantine Station in Philadelphia Can Be Quickly Established —Owing to yellow fever scare now prevalent along the Gulf States the State Quarantine Board of Pennsylvania has become quite active of late and is preparing itself for emergencies which may arise It was recently announced by Dr Henry C Boenning that complete arrangements had been made by the Board of Quarantine whereby the station at Marcus Hook could be provisioned and equipped for 200 persons, within six hours if the emergency arose The Hon John Wanamaker offered to equip the station with bedding, tableware, etc , also cooking ranges Prompt delivery of 100 to 1000 pounds of meat has also been provided for

Contributions for Relief of Sick Soldiers —Mr George C Thomas, treasurer of the National Relief Commission, acknowledges the following contributions received at the banking house of Drexel & Co , Philadelphia Cash previously acknowledged, $56,178 56 , amount cash to date, $621 16 , total, $56,799 66 The St Agnes Hospital acknowledges receipt of $1048, and the Medico Chirurgical Hospital $3580 50 for the relief of the sick soldiers Contributions have also been received by all of the hospitals of the city

Hospital Trains Sent Out from Philadelphia —The following number of hospital trains have been sent to the different army camps by the various hospitals of this city University of Pennsylvania, five , Medico Chirurgical Hospital, five , St Agnes Hospital, one , St Joseph's Hospital one The German Hospital is in communication at the present time with the Surgeon General in regard to dispatching a train for a similar purpose Of the soldiers brought home, about eight deaths have occurred from typhoid fever Dysentery, diarrhea and malarial fever account for the illness of a large proportion of the troops, many of whom have been discharged cured

Avoiding Vaccination in Philadelphia —Dr Ott of the 29th sectional school board questions the genuineness of many vaccination certificates filed at the district school by pupils attending Believing that many papers were irregular, Dr Ott visited the school to make an examination of the scars upon the children, but in many instances refusal was encountered on the ground that the parents objected A resolution however, was passed by the board that the principals of the schools be instructed to make the examination, and also to compare the certificate with that of an accepted medical register

Personal Mention —Dr Ernest Sangree, formerly pathologist to the Philadelphia Hospital, but late professor of pathology and bacteriology in the Vanderbilt University, has returned from a trip to Europe via Philadelphia

Bequest to Charity —By the will of the late Harriet B Evans of this city, a bequest of $5000 has been made to the Presbyterian Hospital as an endowment for a bed in memory of her husband

Washington

Health of the District —The report of Health Officer Woodward for the week ending September 3, shows the total number of deaths to have been 109, of which 58 were white and 51 colored Among the principal causes of death are noted, circulatory, 11 , intestinal, 7 , genito urinary, 3 , respiratory, 9 There were 25 fatal cases of the zymotic class, 7 of which were from inflammation of the bowels, 2 from diphtheria and 8 from typhoid , 3 of the latter cases were soldiers in the Army Barracks There were 43 cases of diphtheria and 39 cases of scarlet fever under treatment at the close of the week

Drs Albert R Collins and F F Repetti have been appointed physicians to the poor

Woman's Clinic —The regular monthly meeting of the Board of Directors of the Woman's Clinic was held on the 3rd instant at the hospital , important business was transacted and the hospital shown to be in a flourishing condition

Associated Charities —The regular monthly report of the Board of Associated Charities shows a marked diminution in the number of applications for help and medical treatment The number of applications for free treatment made to the Central Dispensary and Emergency Hospital was 147 , of this number 109 were granted, 26 were refused and 12 were found to have given false addresses The hospital authorities are very much pleased by the fact that certificates were granted to only 74 per cent of applicants, thus relieving the hospital from the care of about 26 per cent of applicants who would have otherwise imposed upon the institution Ten applicants for treatment at the Woman's Clinic were investigated, 3 of whom were rejected

No More Nurses Required —The following communication was sent to the D A R Corps by General Sternberg

Dr Anita Newcome McGee, director D A R Hospital Corps, Dear Madam —I desire to express to you and to the members of your committee my high appreciation of the valuable assist ance rendered me in the selection of trained female nurses for duty at our general and field hospitals The results have been entirely satisfactory, and I have received most favorable reports with reference to the value of the services of the trained nurses selected through you The demand for nurses is probably about over and in my opinion you could now discontinue your labors in this direction without injury to the service I will therefore make other arrangements for the selection of female nurses, if more should be required, in order that you may be relieved from the arduous labors which have occupied your time so completely during the past four months I desire to express my sincere thanks to you and to each member of your committee, for your patriotic and unremitting efforts, and for your valuable assistance in enabling me to provide for the care of our sick soldiers Very truly yours,

George M Sternberg, Surgeon General U S A

District Surgeons Return —Surgeon and Major R A Pyles, and Assistant Surgeon J H Cox returned to Washington today with the District of Columbia Regiment from Camp Wikoff Both surgeons show the effect of hardship and overwork, but have stuck to their regiment faithfully ever since they left Washington They were warmly welcomed in parade by thousands of friends and admirers Assistant Surgeon Weaver returned some time ago, but has been very ill and confined to bed At one time grave doubts were entertained for his recovery

Detroit

Wayne County Medical Society —The regular meeting of this Society was held on Thursday evening, September 8 Dr David Inglis read a paper on "Dietetic Points" The essayist's first point was what he called the very common and very dangerous fallacy that fruits should be eaten for breakfast He regarded the habit, in city life, of eating fruit for breakfast as pernicious, for the reason that the person who indulges the appetite with such diet is just getting steam for the day's work, his digestive power is at the lowest ebb and the food is of a highly indigestible nature, and must be digested while all of the person's energies are devoted to business and as little as possible to digestion, besides, one who fills his stomach with raw fruit has taken in very little really nourishing food and consequently his body goes hungry The [illegible]ond point in the Doctor's paper was, fruits and vegetables [illegible]ld be cooked before eating as they are more readily [illegible]sted He said "In plain terms, it takes an admirable [illegible]gestion to digest uncooked food and the man or woman who has not a fine reserve of digestive power brings on indigestion by the use of uncooked food Oddly enough, the moment a patient has a bad vomiting spell or an attack of cholera morbus, he searches as probable cause for some raw food or other, but at all other times he quotes medical authorities to prove that it is so very wholesome to eat lots of raw fruit" His next point was *regarding the drinking of water* He said "Our city men and women or many of them, go along with barely enough water to keep from drying up Then they become addicted to pills, tonics, massage, electricity and Christian science—dying for water while the hose is playing in front lawn Our patients need to be ordered to drink systematically, not what they want but what they need" The Doctor next took up the point of feeding typhoid fever patients with milk He condemned the practice in very strong terms, because milk is a solid and not a liquid food, it is a fine culture medium for many bacilli and especially the bacillus typhi abdominalis Pure water, he said, should be given instead of milk

Health report for the week ending September 10 Deaths, 112, births, male 40, female 35, contagious diseases, diphtheria 1, scarlet fever 18

Societies

A regular meeting of the Polk County (Iowa) Medical Society was held in Des Moines September 6 Papers were read by E E Dorr, J W Cokenower and James T Priestley ——A regular meeting of the Lucas County Medical Society was held September 2 ——The quarterly meeting of the Rhode Island Medical Society was held in Providence September 1 ——The McLean County (Ill) Medical Society held a regular meeting in Bloomington September 1 ——The St Clair County (Mo) Medical Society held a regular meeting in St Louis September 1 ——The Belmont County (W Va) Medical Society held a quarterly meeting in Wheeling August 31 ——The semi annual meeting of the Middlesex County (Conn) Medical Society was held in Hartford September 7 ——A regular meeting of the Lyon County (Kan) Medical Society was held in Emporia, Kan, September 7 ——The regular meeting of the Hornellsville (N Y) Medical and Surgical Association was held September 6

THE PUBLIC SERVICE

Major Charles M Gandy, brigade surgeon, will proceed to Huntsville, Ala, and report to the commanding General, Fourth Army Corps, for assignment to duty

Passed Assistant-Surgeon D L Parker, U S N, is honorably discharged, from August 26

Passed Assistant Surgeon N J Blackwood is detached from the *City of Peking* and ordered home

Surgeon W H Rush is detached from the *City of Peking* and ordered to the naval hospital, Mare Island

CHANGE OF ADDRESS

Blitz, A from Sidle Block to Medical Block Minneapolis Minn
Becker F C, from 1751 Milwaukee Ave to 385 W Diversey Ave, Chicago
Bryan G J from Syracuse to Fayetteville N Y
Caspers, P, from 2107 Michigan Ave to 53d and Cottage Grove Ave Chicago, Ill
Cole F M from Hull to Arthur Iowa
Dahl S from 667 N Oakley to 822 N Western Ave, Chicago, Ill
Dal J W from 482 Milwaukee Ave to 499 N Robey St, Chicago, Ill
Elgin W F from Bethesda Md to Glenolden Pa
Frost C A, from Almond to Stevens Point Wis
Gordon R N from Ann Arbor Mich to Realty Block Everett, Wash

ADDRESS

THE CHEMICAL RELATIONS OF REMEDIES IN SCIENTIFIC THERAPEUTICS

Address of the Chairman of the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY JOHN V. SHOEMAKER, M D , LL D
PHILADELPHIA PA

The blood is a nutrient fluid tissue, rich in corpuscular elements The health of the tissues depends upon the health of the blood In the act of nutrition the cells of each organ select their appropriate pabulum The cells are the essential and active components of any organ or tissue In health and disease alike it is the influence of the blood upon the cells that we must study We witness perverted cell action as the result of disease The normal composition of the blood is maintained by the statedly renewed supplies of aliment

As the constituents of normal blood influence the cells according to the type of health, as in disease the activity of the cells is so modified that their functions are very imperfectly performed, so when in disease remedies are given it is still upon the cells that their action is exerted Thus as regards their mode of production, a close analogy exists between the nutrition of health, the disturbances of disease and the action of remedies

As food is obtained from the animal and vegetable kingdoms and includes certain necessary mineral constituents so our remedies are taken from the vegetable and mineral worlds together with some from the animal kingdom, which, however, until recent years were comparatively few in number Within a few years past a variety of preparations have been more or less extensively and successfully employed It is of these and the principles of their employment that I would say a few words today, believing that the subject of tissue therapy and serum therapy is often misunderstood and misrepresented

It was undoubtedly a great advance in scientific medicine when the chemists began to isolate the active principles of vegetable drugs The possession of alkaloids, glucosides, etc , enable us to administer drugs with a precision and efficiency which were formerly impossible A second and, I am disposed to believe, a greater, advance has begun in the introduction of animal tissues, extracts, serums and antitoxins into medicine These methods are yet in their infancy, we are not sure concerning every step in our progress, they are, no doubt, subject in many directions to revision, but they are based upon the experimental work of modern science and may be modified according to future experience When we examine this class of remedies we find that they may be divided into three groups, viz , extracts of glandular and other organs, serums and antitoxins The serums, again, are taken from animals naturally immune to certain diseases and from those who have been rendered artificially immune Correspondingly, as regards their application, extracts are used in the diseases of nutrition and the serum and antitoxins in those due to infection

The doctrine of internal secretion, announced by Brown-Séquard, has been prolific of practical benefit, it has been shown experimentally and clinically that the ductless glands perform a very important office in the economy They elaborate from and return to the blood a material which is necessary to the maintenance of health Other glands which possess ducts for the discharge of their secretions, have been shown, nevertheless, to produce also an internal secretion In the latter class are the testicles and pancreas The testicles were the first organs to be utilized in the treatment of disease When we consider the highly vitalized and specialized character of their secretion we need not be surprised that its loss or suppression should be attended with depression of the physical and mental force Brown-Séquard, therefore, conceived the idea that orchitic extract might be of service in arresting failing nutrition of old age You are all familiar with the incredulity with which this proposition was received Some who tested the new remedy, however, supported the claims which had been made on its behalf and believed themselves warranted in extending its application It has been used with advantage in a number of organic diseases of the nervous system, as locomotor ataxia, chorea and different forms of paralysis In cardiac debility it has also been of service

The most brilliant victory was next won by a ductless gland in the treatment of myxedema The value of thyroid extract in that previously intractable disease has been so conspicuous that negative criticism has been forestalled Under the influence of thyroid therapy the skin softens, the mucoid infiltration lessens or disappears, perspiration returns, the mind clears, the strength increases, the temperature rises and the features lose their deformity Thyroid extract has likewise been of value in relieving cretinism It has been applied to the management of certain other diseases accompanied by depressed nutrition, but although it has accomplished good in some cases it has not been so remarkably successful as in myxedema It was hoped that we might find in the thyroid gland an efficacious remedy for exophthalmic goiter, but our expectations in that direction have not been realized The reports have been scarcely favorable to its use in that disease

The thymus gland has been employed likewise in various disorders of the blood and nervous system, but we are unable to report any decided success from its use Addison's disease stands in much the same relation to lesions of the suprarenal capsules that myxedema does to incapacity of the thyroid gland An extract prepared from the glands has been tentatively used in this disease Experience is not as yet, perhaps, sufficiently extensive to justify the expression of any categorical opinion In a number of instances it has been of undoubted efficacy In some it has increased the strength and relieved the nervous manifestations without exerting any influence upon the pigmentation In others, it has caused a decrease in the coloration as well as improvement in the subjective symptoms The truth probably is that suprarenal extract will benefit such cases as are at all susceptible of improvement When carcinoma or tuberculosis is the cause of suprarenal disease, little can evidently be now expected from any therapeutic measure Nevertheless, some of the cases of Addison's disease which have been ameliorated by this method have apparently been of tuberculous nature The prospect for Addison's disease will brighten if the experiments constantly carried on as regards tuberculosis shall be rewarded by distinct success There are other pathologic alterations to which this disease is sometimes due, and which will probably prove more amenable to the treatment In conclusion, I would say that in a given case it would certainly be be worth while to make a trial of suprarenal therapy

Extracts obtained from other than glandular organs have been employed in the thought that a more direct nutritive supply to the cells might be possible by this means than by those ordinarily employed Extracts of brain and spinal cord have seemed, to competent observers, to have a good effect in neurasthenia, locomotor ataxia, progressive motor dystrophy, senile debility, etc Preparations of cardiac tissue have been injected for asystole, but the most remarkable temporary improvement was in the case of uremia under the care of M Dieulafoy, and to which nephrine was given The case, unfortunately, was too far advanced to be benefited by any mode of treatment, but the temporary results were very striking

Attempts have been made to influence the course of diabetes, more particularly pancreatic diabetes, by using extract of pancreas in such cases Although this treatment had little or no effect upon the quantity of urine passed, yet it often had a favorable influence upon the patient's general condition Pulmonary, ovarian and prostatic juices have been made use of in diseases of the corresponding organs Bone-marrow has given some very excellent results in pernicious anemia

It is fair to ask whether suggestion does not play an important part in the improvement under such methods This may, indeed, be a great factor in the care of functional nervous maladies, but pains were taken, in most instances, to eliminate its influence, and in organic disease suggestion would have less effect

We seem now to stand upon the brink of a new era in therapeutics We look to organic chemistry to furnish us with the active principles of tissues and serums, as it has given us the active principles of vegetable drugs As the active principles of all plants have not yet been isolated, it need be no wonder that in a new field and dealing with complex animal tissues, this problem, for most substances, remains unsolved A beginning, however, has been made The efficacy of orchitic extract depends upon the presence of an organic crystalline substance called spermin, which exists in combination with hydrochloric acid The active principle of the thyroid gland is believed to be the substance isolated under the name of iodothyrin In the same way the antitoxins, in so far as they have been discovered, may be looked upon as the active principles of the immunizing or curative serums Schaefer and Oliver have obtained from the medullary portion of the suprarenal bodies an organic principle which has a powerful action upon the heart, voluntary muscles and peripheral arteries

The serums obtained from animals rendered artificially immune, contain antitoxins, and have proved of more value than those from animals naturally immune to certain maladies The typic instance of success in this form of therapy is diphtheria antitoxin The wonderful reduction in the mortality from diphtheria which this preparation has effected can not be gainsaid Every physician should seriously debate in his own mind whether he has done his duty in a case of diphtheria if he has neglected to take advantage of the immunizing and curative properties of diphtheria antitoxin As diphtheria is such a wide spread disease, every reason, humanitarian and sanitarian, as well as scientific, should combine to make us welcome this important advance in the treatment

Though by no means as common as diphtheria, tetanus is a justly dreaded malady Its terrible manifestations, and the failure of other methods are in glaring contrast to its improved statistics under an antitoxin treatment

I shall merely allude to the progress of laboratory and bedside studies with serum therapy in suppurative diseases, leprosy, cholera and the plague They depend upon similar principles and may require modification as regards many matters of detail, but we may hope that in the end much good will be accomplished by these means The problem concerning tuberculosis has not yet been solved Notwithstanding the great and deserved scientific reputation of Professor Koch, his methods have failed to achieve the desired results Nevertheless, it seems probable that he is working upon correct principles and that success will at length reward his efforts, or if not his own, those of some other observer

Sanarelli is now complementing his brilliant investigations into the bacteriology of yellow fever by the attempt to treat the disease by means of an immunized serum Some favorable clinical results have been reported and it is possible that the comming summer may see some experiments on a large scale among American troops on the island of Cuba It is well known that Surgeon-General Sternberg is personally interested in the subject of the yellow fever bacillus Professor Chantemesse has recently read a paper upon the soluble typhoid fever toxin and antitoxic serum of typhoid fever In this important communication the author describes his experiments upon animals, and concludes in these words "Fortified by these experiments, I injected some antitoxic serum into a patient suffering from typhoid fever The value of this new method of treatment can only be determined by a statistical study and numerous observations I may say, however, that the serum acted well in an antitoxic manner, diminishing and suppressing the nervous symptoms, lowering the temperature and promoting the recovery "

A few years ago Drs G and F Klemperer endeavored to obtain an immunized serum capable of curing pneumonia Some encouraging clinical trials were made, but the serum did not seem to have sufficient strength to be practically useful Others have labored in the same direction, and it has recently been announced that Professors de Renzi and Pane, of the University of Naples have devised a method by which large quantities of a powerful serum can be obtained A series of cases was observed in which very excellent clinical results were obtained in Professor de Renzi's service, and in the *New York Medical Journal* for May 7, 1898, Dr Antonio Fanoni of New York describes a case in which he made use of this method with success

As analogous to the antidotal action of antitoxins and serums, may here be very briefly mentioned the antagonistic action sometimes seen between different diseases Thus, a fever has been known to cause the disappearance of new growths or glycosuria, and impaired eyesight has been improved by an attack of smallpox

It seems that at this juncture we must look to physiologic chemistry for assistance in further progress With the isolation of the active constituents of the various glands and serums which have been thus far experimentally employed, we should be in a position to administer such remedies with greater precision and greater advantage The chemistry of bacteriologic products has already given us a number of substances of definite composition It is now highly desirable that all the organic juices, extracts and serums should be analyzed in order that we may be able to estimate the comparative value of their constituents and study their physiologic action The effect of the animal extracts upon the healthy animal has been the subject of an elaborate series of experiments by Professor Isaac Ott of the Medico-Chirurgical College of Philadelphia What is next of importance in the study of these extracts is that we should be able to determine the substance or substances upon which their activity depends in precisely the same manner as we have learned that morphin is the active principle of opium, strychnin that of nux vomica, ptyalin of the saliva, pepsin of the gastric juice, pancreatin of the pancreatic secretion, etc As, however, pancreatin is not the sole digestive ferment of the pancreatic juice, or morphin the sole alkaloid of opium, so, it may be, the complex organic tissues may contain principles having various actions If these various constituents can be separately prepared and their individual values estimated we may be able to admister them separately or combined, according as they may be indicated This would constitute a step in advance and would enable us to prescribe the active principles of animal extracts with exactitude, just as we can now, at our discretion, order pilocarpin to represent jaborandi, or caffein to represent caffea, etc Another important advantage which would result from the chemical analysis of this class of remedies would be in obtaining standing or uniform products As it is at present, we have a number of animal products obtained by different discoverers and prepared by different processes and having, perhaps, rival claims to our favor Have we not reached such a point in the evolution of this subject that analogous preparations can in this way be standardized? It is necessary that the exact degree of the virulence of the toxins and antitoxins of therapeutic serums should be accurately known and should be maintained at a certain fixed standard, and this point was urged at the recent Ninth International Congress of Hygiene and Demography by Professor Behring It appears that it should now be possible to determine a standard type of serum, especially antidiphtheritic serum, according to which the therapeutic results reported by observers in different countries might be fairly comparable At the congress referred to it was decided that a committee of experts should be appointed to consider whether there would be any advantage in having a uniform international standard of strength in the case of antitoxic serums

The processes by which all these preparations are made should be the common property of the scientific world, just as we have in the United States Pharmacopeia directions for preparing all the official products Different specimens of any crude drug of vegetable origin will give quite a notably different percentage of the active constituent No matter what this variation may be, however, we know that when we make use of an alkaloid or glucoside we are dealing with a substance of definite chemic composition, the same under all circumstances and by whomsoever manufactured Has not the time now arrived when such a work should be begun in reference to glandular extracts and curative serums? We should then appreciate more exactly upon what basis we stood Finally, those which have been proved of value, as, e g, iodothyrin, should be made official and adopted into the United States Pharmacopeia, with full instructions regarding the mode of their preparation The physiologic and therapeutic effects of these active principles of extracts and serums could then be separately determined Their utility in medical practice could be more justly estimated and this new branch of applied therapeutics be placed on a more scientific foundation

This, it seems to me, is the line along which future progress is to be made The entire evolution of the subject under discussion is so recent, it is based upon conceptions so essentially modern, that we need not be surprised if all its promises have not yet been realized The good which has been accomplished in diphtheria alone is an ample reward for the labor that has been spent in its development and a justification for the hope which is entertained of the success of this method of therapy in other diseases It is based upon the most modern doctrines concerning bacterial activity, immunity and mode of cure A powerful trend has for several years been setting in in this direction, and the present status is the outcome of numerous independent or collateral lines of investigation

Immunity is better than cure If an immunized serum is capable of conferring immunity against a certain infection, it will be very readily comprehended that an immense boon has been conferred upon humanity

If it be found that this immunity against an infection is, not permanent, but lasts only for a certain time, it will be an easy matter to repeat the operation at stated intervals upon a fresh exposure, just as we now hold ourselves prepared to repeat the process of vaccination upon the outbreak of smallpox or after the lapse of a certain number of years This is, indeed, nothing more than we observe in nature, for although an attack of one of the eruptive fevers generally confers immunity for life, this rule is by no means universal Other species of infection, as is well known, far from bestowing future immunity, predispose to successive attacks

MODERN TREATMENT OF TUBERCULOSIS

Presented to the Section of Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo, June 7 10, 1898

BY CHARLES DENISON, A M, M D
DENVER, COLO

I am requested by our Chairman to formulate the theories and conclusions on the modern treatment of tuberculosis The object is to bring out your thoughts and excite discussion, and I trust I shall not fail in this purpose As there are no two cases of tuberculosis in a thousand alike in all their various phases, so I might almost say there are no two physicians who will treat these manifestations in the same way, even if they are all recognized, which is a question Our mental appreciation of this most important of the diseases which afflict the human race is in a formative state I fancy one would only have to announce a set plan of management, which he would carry out as suitable to the great majority of his own patients, and the desired controversy would at once be set in motion in opposition thereto

Taking 100 per cent as a basis of what we, as physicians, can do by advice and treatment, and allowing a margin with regard to the great variety in cases, the accompanying table gives the estimate of treatment which I propose for your consideration You may say it is my own conclusion based upon my personal experience with the disease and twenty-five years' practice in Colorado You may also assert that experiences all differ and you can not vote as I do That is just the kind of discussion I am after

Since it is assumed—in which I trust you all agree with me—that the best make-up of the "modern treatment of tuberculosis", is a composite affair, I may state the divisions or heads, with this admission, namely, that they naturally run into each other, consequently some concession is needed in making any divisions at all Notwithstanding the difficulty in pinning medical men down to positive conclusions, which peculiarity may have been brought to your notice, I have tried to make these divisions of our topic fair and just for the purpose in hand, namely, to bring out discussion and, if possible, arrive at some definite conclusion as a basis of a successful fight against this terrible scouge

TUBERCULOSIS TREATMENT TABLE, APPROXIMATE ESTIMATE OF RESULTS

	Proportion of benefits due to	Range of per cent	Average per cent		
1	Climate and change, involving mental influence	15 to 45	30	45	
2	Exercise and out door life	10 to 20	15		
3	Good feeding, special dieting and attention to alimentary canal	10 to 20	15	30	55
4	Medical supervision and medical treatment	5 to 25	15		
5	Inhaling, local medication and surgical interference	5 to 25	15		
6	Specific medication, based upon antitoxin treatment	0 to 20	10		
	Totals, per cent	45 to 155	100		
		100			

I shall devote most of the time allotted to me to the consideration of the last two divisions of this combined treatment Therefore let me save the repetition of my own arguments in substantiation of so large percentages given to the first three of these means by referring to papers I have written [1]

It must also be borne in mind that the physicians' services extend all the way through the last four of these remedial means, i e, have to do especially with a calculated 55 per cent of all that can be done in the way of treatment

The third and fourth divisions should naturally be grouped under a combined head, giving an average of 30 per cent of the total benefit This is perhaps a sufficient concession to this important part of the individualizing process, which it is the duty of the medical adviser to see to in every case

To the fourth division—medical supervision and medical treatment—to which a proportion of 15 per cent is given, it may be objected by some that too little credit is given the professional adviser for what can be done The physician at best is but an aid or guide Mostly all is due to the energy, faithfulness and perseverance of the patient himself To be sure, tonic treatment, strychnia, arsenic, hypophosphites, etc, for "toning up," and guaiacol or creosoted preparations for antiseptic effect, chiefly in the upper portion of the alimentary canal, are entitled to recognition and should be granted a limited per cent of the good we can do The possibility of so saturating the blood with an antiseptic or germicidal agency, such as creosote, that the tubercle bacilli will be stopped in their sporing or growth, and the patient not be injured thereby, is a mere speculation The efficiency of this method, which is at the present time very attractive to a large proportion of the profession, has not yet been demonstrated, further than to show an antiseptic effect in the alimentary canal and upon the lining membrane thereof

The fifth division of our aid—inhaling, local medication and surgical interference—naturally covers a more uncertain field, for not all cases are equally suitable for their employment When the tuberculosis is centered in the upper air-tract, it has been very generally admitted that through inhaling and local treatment medicaments may be made to reach the affected parts, and a staying of the progress of the local disease be accomplished

The doubt has been, however, whether inhaled antiseptic or germicidal agencies ever reached the alveoli and bronchial terminals, where the disease is oftenest located and has its strongest intrenchments This futility of the ordinary and old-fashioned plan of inhaling is a fact It is true that the more a lung is diseased with tuberculosis and the usually accompanying infiltrating and shrinkage process, the less possible is it that inhaled medicaments can reach the affected parts The treatment, whether it be pure or ozonized air, or etherealized or atomized germicides, all goes to the flexible, the healthy, lung

Here again, for lack of time to fully elaborate the argument, I shall have to refer to papers I have written upon this subject [2]

---

[1] For the first means—climate and change involving mental influence—see article on The Climate of Colorado for Respiratory Diseases" published in the JOURNAL for May 7 and 14 1898 I believe this argument warrants the 30 per cent of advantage allotted to this agency of climate

For the second means—exercise and out door life—to which 15 per cent of the total benefit is given, reference is made to the essay on Exercise for Pulmonary Invalids," read before the Congress of Medico-Climatology of the World's Fair Congress June 1 1893

For the third division—good feeding etc —to which an average of 15 *per cent of all good is attributed, reference is made to* Food for Chronic Pulmonary Invalids," read before the Colorado State Medical Society, June 20 1894

[2] Exercise for Pulmonary Invalids," op cit "The air pressure Inhaler and Exhaler," N Y Medical Record Feb 10, 1894 "New uses of the Inhaler and Exhaler" Dietic and Hygienic Gazette, June 1897, and espe-

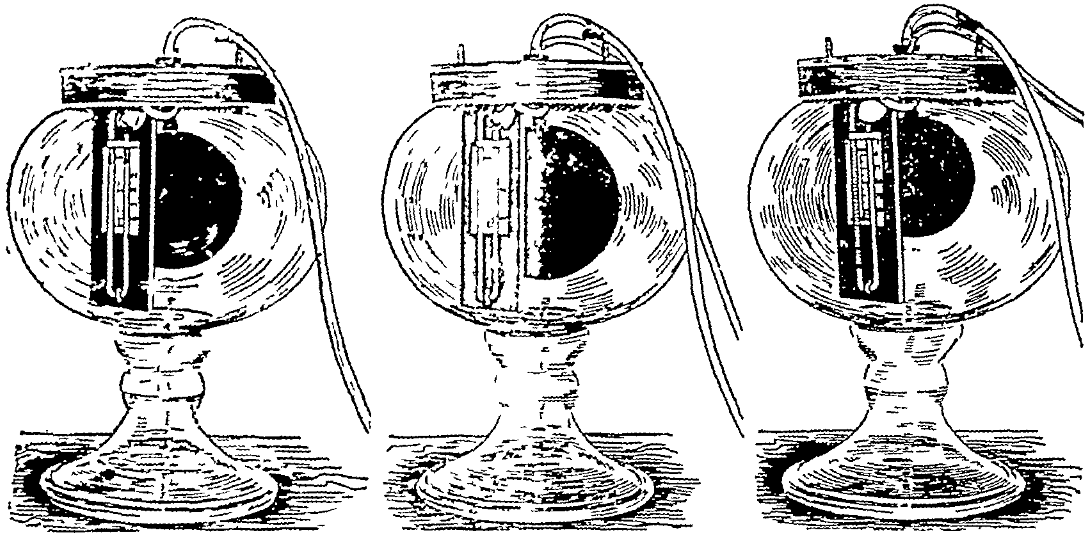
I desire to demonstrate more clearly than has been done heretofore the fact that the correct system of inhaling, or more properly, exhaling, altitude above the sea and rightly directed gymnastic training, all work upon the same principle, namely the *mechanical distention* of the air cells The reciprocal relation of diseased and healthy lung in the same thorax, and of the air and blood within a given chest with reference to respiration, does not seem to me to have been sufficiently recognized by anybody that I know of, unless it be Dr T N McLean of Elizabeth, N J, in his late paper "Personal Observations in Pulmonary Phthisis"

This is perhaps a bold statement, but I believe it is fundamental to a proper understanding of the incipiency, the progress and the control of pulmonary consumption It is quite possible that our inability hitherto to account for the localization of so much of tuberculosis in the lungs, is due to our own fault, because we have failed to recognize the mechanical conditions within the chest which govern respiration and blood circulation [4]

Now, I blow up the air cell, and the condition of air-pressure in the globe, but outside the air-cell, is exactly similar to the pressure upon the blood current within our chests, i e, greater during expiration than during, and in fact, the reverse of, inspiration To prove it pull out the plug and hear the whistle in the vessel's exit opening How well this shows that the blood does not flow alone because the heart pumps it, but because the lung mechanism draws it in and forces it out again How strikingly it shows the preponderance of the expiratory over the inspiratory power of any individual, indicated by the manometer records, proving that it is only during expiration that we have any power at all to distend the air-cells, mechanically closed either by inaction or disease How important then is the use and control of expiration (not inspiration) to maintain the health of the lungs You see how it is that gymnastic training and any system of inhaling, to be of use, must depend upon the habitual mechanical distention of the air-cells, and that from the nature of things, can only occur during expiration The will power given us to prolong and intensify expiration with a fixation of the chest and a lateral expansion of it, due to muscular effort, is our main reliance It enables us to imitate, yes and to healthfully exaggerate, the natural remedial effect of high altitudes in phthisis

THE ILLUSTRATING AIR-CELL (DENISON)

To show the expanding effect of lessened atmospheric pressure upon the pulmonary organs by toy balloon and manometer inside a sealed glass globe



DENVER PRESSURE
5,200 feet elevation, about 12½ lbs to square inch Diameter of cell (balloon) $1\frac{11}{16}$ inch

13,000 FT ELEVATION PRESSURE
9 lbs to square inch, same air in balloon expanded Diameter of cell about 1 [illegible] inch

SEA LEVEL PRESSURE
15 lbs to square inch, same air contracted Diameter of cell about $1\frac{8}{16}$ inch

The *illustrating air-cell*, which I here show you, I have devised to suggest more clearly to the mind these intrathoracic mechanical conditions This three gallon glass globe is to represent the thorax It is, as you see, rigid and should be air-tight The muscular force, to represent living conditions, is transferred to the interior of the globe by an air-pump or by our own breathing power The record of that force, or air-pressure, is given by a manometer inside the globe There is an opening in the cover to represent the exit or entrance of the blood-vessels which are in the thorax This has a valve in it which will whistle when the current is outward Finally, in the center, connected by a tube with the outside, is this rubber balloon representing a flexible air-cell, which you may imagine, if you will, to be one of your own air cells magnified a million times, more or less

A total increase of expiratory power, more than any other agency, can account for the benefit which results to an invalid arriving at the height of 6000 feet in a climate like ours You can see by this illustrating air-cell how it is that he *has* to breathe a fifth more air than he did at sea level to get the same amount of oxygen here as there

It only remains for us to draw out about three pounds of the pressure there is in our glass globe, and you will see the air-cell expand nearly to the approximate conditions on top of Pike's Peak I can then show you the biggest jump that an air-cell ever took—from the summit of Pike's Peak into the Atlantic Ocean! It is simply done by letting into the globe again our Denver air-pressure, and then adding three pounds

---

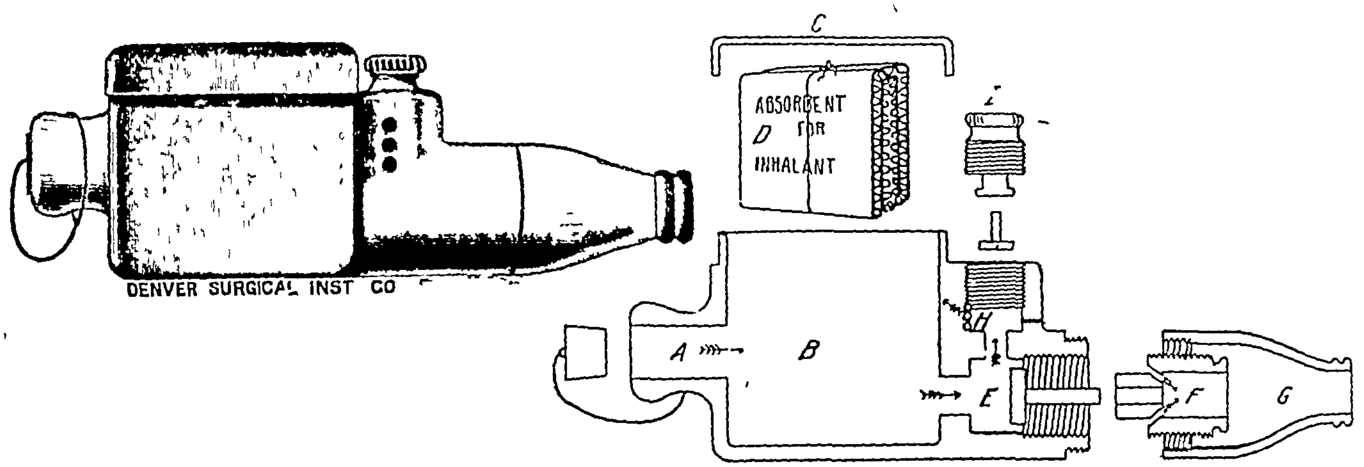
cially one just read before the American Academy of Medicine upon "The Advantage of Physical Education as a Preventative of Disease"

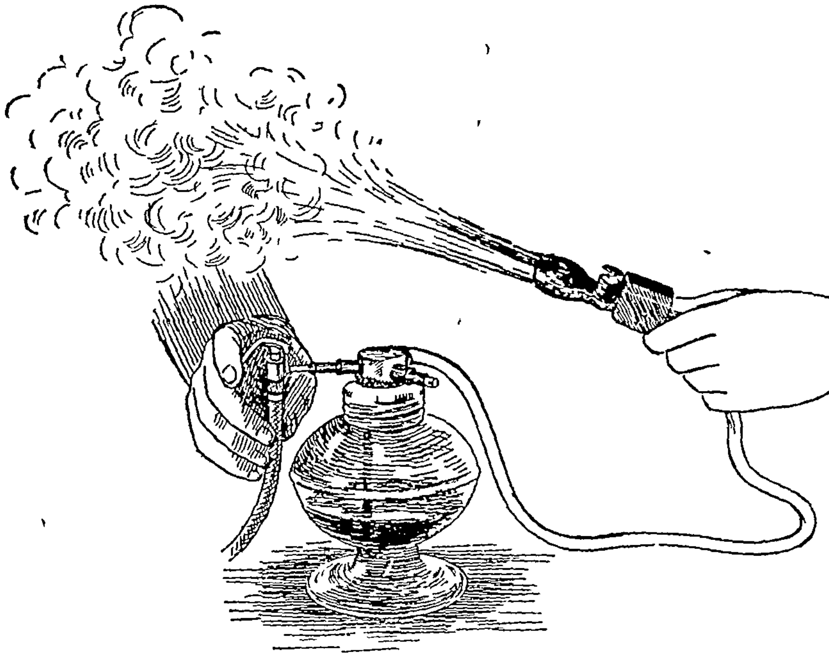
[3] Journal of the American Medical Association Feb 5 1898

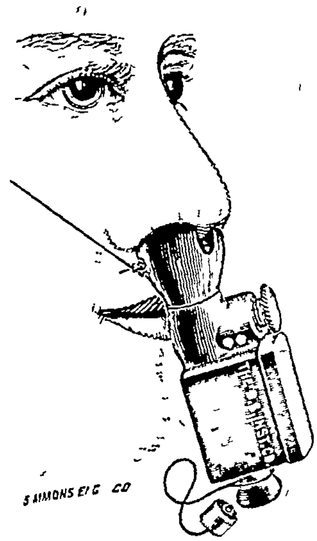
[4] "Abnormal Intrathoracic Air pressures and Their Treatment" by the author President's address American Climatological Association See Transactions for 1890

thereto. The contracted air-cell shrinking from the increased pressure around it, immediately suggests to the mind why it is that low altitudes favor lung inactivity, as it also suggests why it is that the contents of closed cavities, the brain and spinal cord, become congested with blood in the caisson disease.

It was not only as a possible substitute for, but as an imitation of and an aid to, the good mechanical effects of the lessened atmospheric pressure of high altitudes upon the pulmonary air-cells and blood-vessels in disease, that I devised the Inhaler and Exhaler first described in the *Medical Record* in February, 1894. For convenience in pocket form, so that the desired mechanical distention of the air-cells and the needed lateral expansion of the thorax may be had every half-hour or hour in the day, for adjustability, possible according to the strength of the user, whether bedridden or an athlete, and for a means of reaching the air-cells and bronchial surfaces with volatile oils and salts, nothing that I know of has been contrived to equal this device[5].







Physicians who have faithfully used this inhaler, have asserted that 15 per cent of the benefit a pulmonary invalid may get from an average treatment, such as here outlined, is too small an allowance for the good received from this method of inhaling. The effects upon the spirometric capacities and manometer records of invalids, who have used it according to directions as to persistence and energy, have been indeed gratifying.

I have to show you here my own modification of the inhalation of finely atomized volatile oils, a method which is very popular with some physicians as an office means of treatment. Suppose you have by water, or other power, a pressure of 30 or 50 lbs in your office compressed-air reservoir. This is connected thus with a globe inhaler bottle, having an instant cut-off interposed, and this vaporizer in turn is connected by another rubber tube with the Inhaler and Exhaler with nosepiece on instead of the mouthpiece. The delivery is made only during long, full inspirations, and the patient breathes back into the inhaler under a mild resistance of the exit value, so as to get impingement of the medicated inhaled air against all bronchial, throat and nasal surfaces.

There are any number of combinations of volatile oils and germicidal salts possible to be employed by this method, but something like the following combination I have found to be most satisfactory for average cases.

℞ Ol eucalyptus (Tyndale's) 20 to 40 per cent, carbolic acid crystals 10 to 30 per cent, oleum pinus Pumilio (Merck's) and liquid guaiacol (Schring & Glatz), of each 5 to 10 per cent, oil of cloves and cedar, of each 2 to 5 per cent , and formalin one half to one per cent

---

[5] The Denver Surgical Instrument Co.

With this combination medicate your vehicle, whether it be liquid vaselin, glymol or albolin, to suit mild, ordinary uses Then, for extra antiseptic or stimulating effect, the absorbent in the medicament box can be additionally medicated with formalin or other germicidal means for temporary use This finely atomized spray you can see, as one who breathes it can feel, reaches all open spaces even to the ultimate air cells, for considerable of the vapor returns with expiration, thus showing that some of the medicament has not been condensed What proportion of it has been we do not know, but the results in tubercular affections, especially with "grip cold," hypertrophic rhinitis, ozena, laryngitis, bronchitis, etc , are quite satisfactory

I have included an allowance for surgical interference, which is an important field in bone and joint tuberculosis, so called scrofulous gland affections, lupoid skin diseases, laryngeal ulcerations, adenoid growths, tubercular pleurisies, etc I must, however, here put in my protest against the surgeon's hasty interference in operating upon fistulæ in-ano while tubercular infection is at all active in the lungs I believe we should consider these fistulæ as eliminating means on the conservative order, and unless substitutive elimination is provided for, an operation should not be performed

There is certainly no lack of opportunity for discussion with reference to our sixth and last subdivision of treatment, that of specific medication, for the very fact of there being any specific or antitoxin treatment of tuberculosis will be called in question This opposition exists, notwithstanding there are on every hand around us, instances of acquired immunity to tuberculosis, though perhaps limited in degree Wise professors will confidently state that it is "a will-of-the wisp" to even seek such an agency as may be termed a specific for tuberculosis Yet if the disease is due to a special toxin working in the system, it must be only through the development in that system of the appropriate antitoxin, or by the addition of it when created outside the body, that sufficient resistance can be had to stay the progress of the disease Such resistance is what these opponents are after, whether by the means of tonics, exercise, or climates Yet they would seemingly call in question the very source of that natural resistance, namely the natural or artificially created antitoxic condition of the blood or tissues, which is antagonistic to further tubercular infection These opponents then seem to admit the existence of a toxin, but deny that of an antitoxin

Leaving open for discussion the question of fact as to the existence of an antitoxin or specific (for tuberculosis), created or existing outside the human body, I am going to assume that the creation of such an antitoxic agency in the affected or infected system is admitted, and that that existence or mode of resistance is in perfect harmony with nature's methods in eliminating other specific diseases

We will then divide the antitoxin treatment of tuberculosis into two distinct methods the *direct* and the *indirect* These two should not be confounded with each other, as is the habit of some men in speaking of the tuberculin treatment

The former, the direct method, is that inaugurated by Koch as the outcome of his discovery of the bacillus—the reputed cause of tuberculosis Under the limited knowledge of the agency and of the disease it was to cure, this remedy soon demonstrated the need of an advanced chemistry in the technique of its preparation, and an enlightened skill in its administration beyond anything which existed in the scientific world Since this discovery, the eight years of study and investigation of a few faithful observers, under most difficult and discouraging conditions imposed upon them by an onlooking and rather belligerent professional brotherhood, have served to develop a limited improvement in the particulars just named I might say that this improvement in chemical technique, and afterward in administrative skill, had been considerable, if any due recognition of it had been manifest on the part of the medical profession as a body This I will say, however I firmly believe that tuberculosis could be held in check, if not cured, by this means, up to the proportion of, and even beyond, the 10 per cent allotted to it in our table, if, with the present advanced technique in the manufacture of these direct tuberculin preparations the physician using them had the required knowledge to discriminate what patients could be treated by this method, and how far the treatment should be pushed He should not only know the strength of his remedies, but also the *percentage of infection* with which he has to deal It is a most gratifying and successful method of treatment if the condition favorable to its success can be secured But the technique must be exact, and the general and individual objections to the use of such an antitoxin-creating remedy must be recognized Thus, a knowledge of the applicability of the treatment narrows down its use to a small field For instance if the powers of nature are already over taxed in an antitoxin effort, as in acute or miliary tuberculosis, nothing but harm can come from any increase of nature's burden

It is likewise absurd to expect to reach with this treatment, closed or open spots, as cavities in the lung, or shut-in ulcerated regions where the blood does not circulate And yet, most cases of pulmonary consumption harbor these conditions, many of which I believe are never recognized If the treatment is inadvisable in caseous pneumonias and acute conditions, then I conceive it is quite possible that in some serious cases not acute, the massage, first recommended by the Germans as an auxiliary aid, may do damage by loosening up toxic material, and surcharging with it the blood already overloaded However, if either incipiency of tuberculosis, or a chronicity, which is its equivalent—and chronicity brings equivalence because of some already acquired immunity—is known to exist, there is then no question but that the direct tuberculin method is the natural method of cure

If time permitted I would elaborate this theme However, I trust it will be acceptable to show a few of the cases I might call upon in this vicinity, who have become pretty thoroughly immunized against tubercular infection chiefly through this method I have chosen ten cases, mostly those treated with Koch's crude tuberculin, from three to over six years ago, and have asked them to be present that you might verify their healthy appearance These cases are purposely selected as those upon which the influence of climate has been very slight

Case 1 —Miss N S over five years ago treated with Koch's tuberculin Diagnosis then made with tuberculin, there being no expectoration Physical diagnosis then indicated First stage both apices, and tubercular disease of the right hip joint, due to injury four years previously, took as high as 160 mg of tuberculin to the dose before a four months' course was ended Had walked on crutches for over three years previously, but soon, and while under treatment, discarded them, Finally could step up stairs, raising the injured limb first, something she had been unable to do for four years Weight, strength and all symptoms improved during treatment—weight then 110½ pounds, now 146 pounds and she walks without the limp she used to have She has lived in Colorado since 1881, and climate had very little to do with it This case is the same reported as case 2 "Favorable Results of Koch's Tubercular Treatment in Tubercular Affections that are not Pulmonary," in the *New York Medical Journal*, Aug 3, 1895

Case 2 —C F M had been four years ailing, and had lived in the Rocky Mountain regions most of that time, when I first saw him in July, 1892 He was shown to be tubercular by microscopic examination of sputum, had a large cavity in right infrascapular region, say 2 by 4 inches in size and softening to the extent of excavation on opposite side, from which spots he was bleeding on any exertion Had been confined in bed five weeks on that account His hemorrhages were stopped by mechanical means, a properly adjusted harness or chest corset and tuberculin treatment was gradually instituted This was distributed over different periods during the following two years, and he took as high as 240 mg crude tuberculin for the largest dose Accidents have occurred from mechanically straining the large cavity in his right lung, which cavity two or three years ago assumed the shape of a cucumber or banana Three years ago, when, under protest, he went to live in Leadville, Colo, he had hemorrhages, and they have been repeated at other times, but his remarkable vitality and considerable immunity each time have brought him through Of late years, without tubercular activity this case has assumed the conditions of purulent bronchitis *i e*, coexisting contracted cavity and bronchiectasis There are now purulent evidences, but seldom any tubercle bacilli found in his abundant expectoration Both of these cases are remarkable, and each by itself sufficient for a whole paper had we time to elaborate them

Case 3 —S T B, in April, 1893, was brought to me by his father, who had come to take him home to Pennsylvania, as in Colorado Springs hope of his recovery had been abandoned He had reached the stage of tubercular softening in both lungs and had been affected three years, the last six months of which time he had lived in Colorado The susceptibility to crude tuberculin was gradually overcome and he took considerable quantities of this or the antiphthisin (Kleb's) Since his immunity became established he has enjoyed excellent health

Case 4 —F E D Period of incipiency uncertain, perhaps two years Arrived in Colorado in July, 1895, when he had "mixed infection" bacilli in sputum and first stage of tuberculosis in left lung Soon thereafter a small nodule came on scalp, in which, when it softened, a tubercle bacillus was found While undergoing the first immunization with tuberculin he injured his elbow in a fall and that joint became tubercular during the resulting inflammation The periostium of the ulna was affected, with probably some implication of the elbow joint, as, in a subsequent operation performed by Dr C A Powers, some of the joint fluid exuded After laying bare and scraping the bone healing was greatly aided by a continuation of the immunizing process This did not entirely remove the difficulty, and some two years ago a second operation was performed, at which time the ulna was drilled through and quite a piece of necrosed bone removed The recovery under antiseptic packing and the treatment with antiphthisin was most excellent, only slight evidences of bone and joint disease remained and no trouble whatever with his lungs A year ago he returned to his Vermont home On coming back to Colorado last winter he had an attack of la grippe and that focusing agency in tuberculosis seemed to excite the latent disease of the affected elbow joint into activity The swelling, immobility, pain and ulceration portended the possible necessity of resection or amputation A very satisfactory test was made with crude tuberculin, warranting a renewal of specific treatment, this time with Von Ruck's purified tuberculin and ending with the "watery extract" Nothing could be more positively demonstrative of the good effect of the course pursued than the subsidence of swelling, soreness, lessening of the local discharge and general improvement which immediately resulted, in fact apparent complete recovery Here is a study for those surgeons who scoff at tuberculin It should convince them that there is a mild and immunizing power in this agency beyond their ken—something which may prevent the necessity of the use of the knife in many cases and perhaps warrant its use in others previously considered inoperable

Case 5 —Miss N McK is another surgical case in which the influence of climate seemed to have already been exhausted, for she had nearly recovered from the lung disease for which seven years previously she had come to Colorado This is the scrofula gland and first stage case previously reported[5] In February, 1896, Dr Powers, assisted by Drs O'Connor, Pedersen and myself, removed from the right side of this woman's neck sixteen or seventeen glands which together filled a teacup On that side they had commenced to ulcerate and there were nearly as many more on the left side, filling the depressions from the ear to the clavicle These latter not being so far advanced, were deferred for a future operation Encouragement to continue this immunizing process was afforded in the gradual shrinkage of the remaining glands and general improvement of the patient as treatment progressed You see now, after two years only the remnants of those scrofular swellings on this left side

Case 6 —J T U, treated March, 1892, for tuberculosis (bacilli in sputum), which seemed to have reached the second stage in the rear base of left lung He had had some trouble, combined with pleurisy there, coming on for four years Now he is a fine specimen of health His treatment with considerable doses of crude tuberculin was before the discovery of any improved modification of the drug

Case 7 —G T S Treatment commenced before the last-named, six and one half years ago Reacted profoundly to 2 mg crude tuberculin giving from the normal a temperature rise to 103 degrees F The treatment was pushed and there were no reactions to the 20 mg dose It was continued to 50 mg and then stopped He has had little medical attendance since

Case 8 —C R, affected half a year when he came to Colorado, three and one half years ago He had pleurisy at base of left lung, in the apex of which softening had occurred, and there were first stage symptoms on right side, bacilli in sputum, etc Since immunization three years ago he has gone through typhoid fever His condition of health at the present time is something to recommend any course which will accomplish so much, even admitting climatic influence, physical exercise and faithful co operation of the patient as aids

Cases 9 and 10 —Husband and wife Wife first treated four years ago and husband two years Both had excavations, wife in apex of right and husband in upper part of the left lung toward axilla Wife first treated with crude tuberculin, husband with antiphthisin Both of these, for seeming loss or insufficiency of immunity, were again treated last fall with Von Ruck's "watery extract of the dead bacilli" Others of this list besides these two have shown the happy return to the tuberculin effect when a renewal of the treatment seemed necessary A patient once benefited by tuberculin may in three months to two years reveal a certain loss of his acquired immunity, thus showing how relative to one s infection is his own resistance

If a reason is required why so small a ratio of possible relief is attributed to this specific treatment by one who believes in it as I do, let it be understood that only a small proportion of the tubercular cases coming to Colorado are selectable for this method It ought also to be recognized that the failures with tuberculin have been due not so much to inefficiency as to the lack of knowledge on the part of the physician how to discriminate cases fit for its use, as well as to a disinclination to attend to needed details in the technique of its administration

I regret the lack of time to go more fully into details, and the necessity, therefore, to somewhat summarily dispose of the second method of the antitoxin treatment This is the indirect method, wherein, instead of exciting in the human body a resisting antitoxin to a given disease, it is created in an animal and then given gratis to the invalid In the former (the indirect) method there are two speculations which are severe enough tests to be sure 1 the toxin remedy, and 2, the uncertain patient, while in the latter (the indirect) method there are three additional speculations These are 3, the choice of the animal, chiefly with reference to its natural immunity to tuberculosis, *i e*, whether the dog goat, ass, horse or lion is best In fact, to what extent a natural immunity to this disease, admitting that it must be relative to surrounding conditions, can be conferred through the blood serum to a human being, is an open and undetermined question 4 The quantity and quality of the immunizing toxin to be administered to an animal whose serum is to be used This is a reasonable speculation not yet removed from the realm of uncertainty 5 The time said animal should be treated, both before the injections are stopped and afterward, before the blood is drawn, is an important speculative point Dr G T Hunter, who is present, has kindly presented me with some lion's serum, which was taken from an animal kept under the most favorable immunizing conditions up in the mountains of Germany Treated nine months, at first with highly virulent doses of tuberculin toxin, with gradual cessation as immunity was reached, and a whole month allowed to intervene between the last injection and the taking of the serum Whether that procedure is the proper one or whether with different animals this may not be waiting too long for the best results, is a question of speculative nature The burden of proof as to these three extra objections rests with the advocates of this indirect method My own good success with horse serums during the first four to six weeks' treatment of a dozen or more patients was perhaps due to personal precautions, i e , not increasing any dose which gave a reaction to the previous treatment, and not, as directed by the manufacturers, giving daily, but instead, every other day injections The after evidence of the possible cumulative effect of such mixed foreign substances, introduced into the blood of a patient, led to a fear that the resistance to the disease in individual cases was overtaxed The unfavorable results of other physicians, who crowded this treatment according to recommended rules in printed directions, served to confirm the conclusion that an antitubercular serum is a mixture, the exact proportions of the converted toxins or antitoxins in which we do not fully understand The serum treatment of tuberculosis, as yet, is a beautiful dream, which I for one profoundly hope will be realized

---

[5] The Microscopic Proof of a Curative Process in Tuberculosis Transactions Colorado State Medical Society, twenty sixth annual meeting

Pardon the extension of this paper and do not lose sight of the arbitrary divisions of treatment given in the table presented for the purpose of bringing out in discussion your various views

To sum up, the following conclusions are advanced

1 As a part is greater than the whole, the combined method is superior to any given branch of the treatment The individualizing process, and the adaptation of all methods to the needs of a given case, is the preferable plan

2 The seasonable change of residence to a well-selected high-altitude climate, with its dryness, sunshine, possibilities of out door life, and its stimulating qualities, gives the best possible resistance to the advance of consumption

3 Exercise is most essential and necessary to promote both cell activity and the needed mechanical distention of the air-cells

4 Local treatment and proper inhaling methods bear important relation to exercise, cell stimulation and the climatic effect by the high altitude method

5 A great and most valuable addition to our curative means comes through the skillful determination of the proportion of infection, in order to know the balance between bodily resistance and the disease This balance is the key to the as yet preferable—the direct—method of specific treatment

6 It is a mistake to overwhelm the body with frequent injections of undetermined animal serum, thereby producing either a severe reaction or a possible cumulative toxemia

---

ANTITUBERCLE SERUM (PAQUIN) IN TUBERCULOSIS

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY WILLIAM HUTSON PRIOLEAU, A M , M D
SUMMERVILLE S C

At the forty-seventh annual meeting of the South Carolina Medical Association, held in April, 1897, I had the pleasure of making a detailed report of cases of tuberculosis treated with antitubercle serum (Paquin) this report was afterward published in the *New York Medical Journal* of June 26, 1897 In this paper I shall endeavor to add to that report by giving my conclusions as drawn from a three years' experience with this serum I shall try to point out when to use it and when not to use it, also that it is not a specific, but a treatment of inestimable value when used in conjunction with good climate, diet, etc

A careful observer can not fail to notice that one by one the diseases which in years gone by have produced the greatest mortality are now slowly but surely yielding to science and scientific treatment This is all the more true because we are giving up empiricism for rationalism, drugs are used less and antitoxins more All of us rejoice in the antitoxin for diphtheria, and use it because the American Pediatric Society has put the stamp of approval on it, many of us use antitubercle serum (Paquin) because we have tried it and found out its value from clinical observation and by actual experience Dwelling as I do in a winter resort for consumptives, naturally I see a great many cases each year Since beginning the practice of medicine at Summerville, S C , I have been anxiously looking for some treatment to benefit these poor unfortunates, if not cure them Various kinds of treatment have been vaunted to the skies, but none has given me the real satisfaction that antitubercle serum (Paquin) has I have used it for three years, and during that time I have alleviated the sufferings of many, prolonged their lives and seemingly in some cases have produced cures I say seemingly, because three years is too short a time to say positively whether one has been cured or not In order to test the serum thoroughly, I used it on all cases that came into my office, irrespective of the stages In this manner I treated twenty or more, only one being in the incipiency, out of this number all but two were benefited, some being temporarily cured, others apparently cured The cases were pulmonary, laryngeal, glandular and joint, and the serum acted equally well on all It is, however, as well to know when not to use the serum as when to use it, because on its proper application depends its value From my own experience I have come to the following conclusions, viz

1 That antitubercle serum (Paquin) is nearer a specific for all kinds of tuberculosis than any other treatment

2 That it is most valuable in pure, unmixed tuberculosis, that is, tuberculosis uncomplicated with some infection

3 That it ought to be used in the pretubercular or incipient stage and in the beginning of second stage

4 That it ought not to be used with eat h

when there is a daily rise of temperature to 102 degrees

5 That given by the rectum the results are equally as good as when given hypodermically

6 That rectal injections never cause any unpleasant symptoms, as are occasionally produced hypodermically

These conclusions, as I say, are based on actual experiments in private practice, and necessarily must be of value to any one using the serum Most of us, when giving a new treatment a trial, are apt to use it on an old case as a last resort, everything else having been tried This helps neither the patient nor the treatment, perhaps it may benefit the former a little, but most assuredly injures the latter It is also of great importance for us to make an early diagnosis in all cases, and if possible to begin treatment in the pretubercular stage Each and every year many precious lives are sacrificed on the altar of physicians' carelessness in examinations No matter how slight the trouble may be, he ought to be able to locate it Our examinations should be both physical and microscopic It not infrequently happens that on physical examination we detect a lesion, and at the same time a microscopic examination of the sputum fails to show up the tubercle bacilli One examination in such a case should not suffice, we should make them at stated intervals until some positive diagnosis can be made

In tuberculosis all of us recognize a wasting disease, such being the case, we must not only endeavor to arrest or destroy the germs by antitubercle serum, but also endeavor to surround the patients with such conditions as are most conducive to convalescence I shall not dwell on this point, I only wish to call your attention to the fact that this antitubercle serum deals only with the tubercle bacilli, and that it is also necessary in addition to put the patient on flesh-producing food, tonics, and in a good climate It has been my experience that tubercular patients improve more rapidly in a low altitude than in a high, because as a rule they all have weak hearts, and the higher the altitude the more strain on the heart I shall not weary you with a detailed report of all my cases, but there are four to which I would like to call special attention

Case 1 —Young man, aged 28 First hemorrhage in October, 1897, followed by fever and night sweats Cough troublesome No appetite Came to Summerville in March, 1898 Put him on the serum treatment—rectal injections Improvement began almost immediately He was allowed to return to his home in Georgia to carry on the treatment Last reports of his condition are good Says he has never felt better in his life and weighs more than his average weight

Case 2 —Male, aged 28 years Family history good Contracted phthisis pulmonalis in February, 1895, after having been weakened by two successive attacks of grip Physical examination showed one spot on apex of right lung, and another in lower part of upper lobe of left lung, posteriorly It was a typic case, with fever, cough, night sweats, hemorrhages, etc The patient was ordered in May, 1895, to the mountains of North Carolina, where he passed the summer with little or no benefit He then came to Summerville in the autumn and remained for two months, when tuberculosis of the hip and testes developing, he was advised to go to Charleston for the purpose of having an operation performed There his testes were operated upon, but he refused to have his hip joint opened The pain in the hip had become so intense that the slightest movement in bed would cause extreme agony At my earnest request the physician in charge kindly consented to treat him with Dr Paquin's serum, and it was not very long before his hip became much improved So great was this improvement that in a few months the patient was enabled to walk without the help of crutches and with absolutely no pain In every respect he continued to improve and finally in March, 1896, he returned to Summerville There I continued the serum treatment until the hot weather set in, at which time, for numerous reasons, I stopped it Not three weeks after its discontinuance the patient developed tuberculosis of the brain, which in the space of two weeks caused his death

This case is interesting in many points First the development of tubercles in the lungs, followed by tubercles in the testes, hip and brain, also because of the marked and immediate relief furnished him by Dr Paquin's serum And lastly, because it was the only case in which I have observed alarming symptoms caused by a hypodermic injection of the serum

Case 3 —Woman, aged 35 years Family history negative Patient had suffered from repeated attacks of the grip In the last four years it was her custom to come south for the winter season An examination revealed a lesion in the upper part of the right lung, I could not say whether it was tubercular or not A careful examination of the sputa did not show tubercle bacilli There had been no improvement in health during the last three winters, so in 1897, I placed her under the serum treatment Immediately after using this serum improvement became quite noticeable, and after three months' treatment I allowed her to return home, not, however, without cautioning her to be extremely careful with herself, and for the next year to use twice a week rectal injections of Dr Paquin's serum, forty minims at a dose In March, 1898, this patient reported continued improvement

Case 4 —Male, aged 25 years Family history poor Father and sister had died of phthisis pulmonalis Patient has had a cough all his life In June 1896, he had several hemorrhages, also fever, night sweats, cough, etc On examination I found consolidation in upper part of lower lobe of left lung I immediately put him under the serum treatment, with no other medicines Very soon his hemorrhages ceased, his night sweats were arrested, and his fever left him His appetite was restored and his strength renewed Improvement continued until the summer, when the injections of serum were discontinued because of the great difficulty in keeping the serum fresh In the fall I commenced to inject him again, and since that time he has steadily improved His gain in weight is eleven pounds, and he coughs only when the atmosphere is damp and moist I advised him that he could return to his work, but that for the next year he must use the serum by rectal injections twice a week This case is worthy of observation, because of such a brilliant and successful result in one who so strongly inherited a predisposition to tuberculosis

April, 1898 —During the past winter he has coughed a great deal, owing to a discontinuance of the serum contrary to my advice, but is now better and at work again, having resumed the serum treatment

Finally, I want to say again that another year's experience with antitubercle serum (Paquin) has convinced me more than ever of its merits, and I feel sure that after giving it a fair trial you will likewise be convinced

---

THE STUDY OF MATERIA MEDICA AND THERAPEUTICS

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo,
June 7-10 1898

BY HENRY M BRACKEN, M D
Professor of Materia Medica, Therapeutics and Clinical Medicine
University of Minnesota Secretary and Executive Officer
of the Minnesota State Board of Health
MINNEAPOLIS

My views upon the subject were given under this title in the *New York Medical Journal,* May 2, 1896 Some points set forth will be emphasized in this paper The object of study is twofold first, to train the mind, second, to give the student knowledge that he can make practical use of In this age of utilitarianism, the first object is often lost sight of Teachers of medicine and surgery may even speak of the study of materia medica as useless Their opinion is based upon the fact that the older one is in the practice of his profession the smaller will be his list of therapeutic agents They argue that a student will pick up the necessary knowledge relating to important drugs, in connection with his clinical studies This is certainly a mistake The best therapeutists are men who are thinkers, not machines The practitioner who uses a therapeutic agent because he was trained to do so by his clinical teacher in his student days, will soon become a back number The agent may have been the best of its kind in his student days, but the rapid progress that is now possible in therapeutic knowledge may soon displace supposed valuable products by others which prove themselves of greater value Therapeutic knowledge is becoming more exact each year, and this is due largely to the work of the pathologist and the physiologist

There are three methods of teaching materia medica by lectures in the pharmaceutical laboratory, in the physiological laboratory It is quite common for a school to adopt one or the other of these three methods, to the exclusion of the other two This is a mistake No student should commence the study of materia medica unless he has had at least a year's work in chemistry and physiology This would prepare him to understand the terms that are in constant use in the study of drugs The lecture room is the place to begin the study of materia medica The process here is one of general instruction, of bringing together the important chemic, physiologic and pharmaceutic facts Drugs that have little value can be described briefly by the lecturer, and then receive but little further consideration by the students—possibly never be thought of again, or possibly be brought out and used to good purpose at some future opportune moment The important drugs should be given due prominence by the lecturer It would be hard for the student to grasp the necessary points connected with the study of drugs were he to depend upon his own judgment, but a few words from the lecturer should make the way clear to him Without such help the student would have to wade through a mass of material, and would be unable to separate the wheat from the chaff For example consider the study of opium Without a guide a student would be thoroughly confused by the number of active principles and pharmaceutic preparations Let the lecturer go over this subject with his class, drawing attention to the fact that a knowledge of a few of these preparations is quite sufficient, that, in fact, it would be no great loss if one knew nothing of the opium preparations, provided his knowledge of morphin was accurate The use of any opium preparation is to secure the action of morphin, so that direct dosage with morphin should be more satisfactory in every way than the use of opium in any form So also with the preparation of iron The uncertainty as to the true therapeutic explanation of the action of iron, together with other bases for theories, has been an excuse for introducing a remarkable list of preparations, official and non-official The student is quite embarrassed by this display of titles A few words from the lecturer, however, may reduce this confusion of the iron preparations to a few simple principles—stability, local action, remote action, etc —and thus make the actual knowledge required an easy matter All these points are as easily given, by lecture, to a room full of students as to small sections of a class There is also a great saving of labor by this method The lecturer thus paves the way for the laboratory instruction In laboratory instruction, pharmaceutic work should be taken up first This should be taught by a medical man with a pharmaceutic training, rather than by a pharmacist with a medical training, otherwise the pharmaceutic knowledge imparted to medical students is apt to be overdone The teaching should be most practical The course must necessarily be short, for there are many other important things to take the student's time The medical student does not need to be a pharmacist, but he must have sufficient pharmaceutic knowledge to enable him to write prescriptions intelligently

After the pharmaceutic training, the student is ready for the physiologic laboratory, where he may study drug action This should be the most interesting part of his work in materia medica It is the most difficult part for the instructor The work must be done by the class in small sections The experiments, even in the hands of trained men, are often failures, for one reason or another This work often takes a great deal of time and yields very poor return from the student's standpoint The study of the physiologic action of drugs is by no means a simple task, and it is an open question whether it might not be better for the general medical student to accept the conclusions of some eminent physiologist, as to the physiologic action of drugs, rather than try to demonstrate such action for himself It is a question whether the study of drugs in the physiologic laboratory should not be limited to demonstrations, by the instructor, of a few important truths It certainly is a question whether the student's individual work along this line should not be classed with the advanced work of the senior year, if taken up at all He may then be able to apply his combined student's knowledge to the task before him It is even a question whether the special physiologic laboratory study of drugs should not be made an elective course, so that only those who have a special liking for such work would take it up

Thus we have the work of the lecturer and of the laboratory instructor combined The lecturer is an educator in the broadest sense, the laboratory instructor is a practical demonstrator, more important, in a way, than the lecturer, but more restricted in his work

The student is now prepared to take up his work in therapeutics This naturally comes in the third year of a four years' course Therapeutic agents are best studied first in groups, according to action, as anodynes, antipyretics, analgesics, etc The demand for a therapeutic agent naturally suggests one of these groups In each group there will probably be but three or four important therapeutic agents The student learns naturally, through this arrangement, to eliminate those that are unimportant At the same time, a little reasoning will enable him to appreciate the advantages one agent may have over another of the same group, in any given case It will also prepare him for the necessity, which sometimes arises, of changing from one agent to another of the same group, under certain conditions, in order to secure the best drug effect, and at the same time, to avoid establishing either a drug tolerance or a drug habit When the student learns his therapeutics in this way, he will have little inclination to become a prescription copyist, and his tendency will [illegible] he writing of simple prescriptions, r[illegible] polypharmacy In this system [illegible] peutics, it becomes unnecessary [illegible] devote time to the therapeutics of each and every drug separately He gives, in common, the points to the whole group, and then points out the advantages and disadvantages, the importance or the uselessness, of each agent in the group Naturally, he would devote a considerable time to the therapeutic properties of the important agents In connection with this course, the student must become familiar with prescribing Three methods of using drugs are now in vogue the hypodermatic method, the bedside dispensing of drugs, the use of prescriptions The student would readily become familiar with the first and second methods The third method is a little more difficult to follow Instructions should, therefore, be given in prescription writing, drawing attention, not only to the action of drugs prescribed, but to the form of prescription, compatibility of parts, both chemically and physiologically, and last, but not least, if the prescription is for internal use, its palatabilty This work should place the student in good form for his duties at the bedside

The work that I have so far outlined, as belonging to therapeutics, should occupy time extending through the third year of a four years' medical course In the senior, or fourth year, the work in therapeutics should be continued, but along very different lines from those pursued during the previous year's study There should now be an application of the knowledge which the student has already acquired The therapeutic teaching should be connected with clinical work It is not enough to study a case simply to arrive at a diagnosis That may satisfy the physician's curiosity, but it will not satisfy the patient Something must be done to cure the patient, if possible If this is not possible, it is at least necessary to do all in one's power to guard against complications, to pilot the patient through to a safe termination of his troubles, or to at least produce euthanasia when dealing with those cases where death is the only ending for suffering There are nihilists in therapeutics, but these are men who are not willing to consider the comforts of their patients We should take great pains not to have any therapeutic nihilists among our students The instructor in therapeutics for this final work should be a clinical teacher, one who appreciates the points I have just referred to as bearing upon the comfort of his patients

I have thus outlined the teaching of materia medica and therapeutics to extend over a period of three years This has not been with the purpose of loading a great deal of work upon the medical student, but rather of giving him a little at a time, in order that he may understand the subject thoroughly The work could be done in one year, as far as time is concerned, but it would then be simply a process of cramming, and the results could not possibly be satisfactory

---

SOME PREPARATIONS OF THE NATIONAL FORMULARY

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY C LEWIS DIEHL, PH M

LOUISVILLE, KY

At the meeting of this ASSOCIATION in 1893 I had the honor to read a paper[1] before this Section, in which I outlined some of the conditions that have had marked influence upon the practice of pharmacy in its relation to that of medicine I pointed out that the modern practice of prescribing medicaments of special manufacture had become a burden upon the pharmacist which, if not relieved, would surely end disastrously to those who, adhering to the ancient landmarks, strove to supply their patrons with medicaments of their own manufacture or of generally recognized and officially accepted composition Indeed, the thought has impressed itself more and more upon my mind, that if physicians had entered into a conspiracy to drive the educated and qualified pharmacist out of business, they could not have pursued a more certain method than that which has become a common practice during the last decade In my personal experience, drugs, chemicals and pharmaceutical preparations which were considered indispensable under the older practice now remain unused on the shelves or become ruined before they can be disposed of, and this in face of the fact that these same drugs, chemicals or preparations are the component parts of, or are represented by, the preparations of special manufacture now popularly prescribed

So simple a drug as gentian root is made into a palatable and sightly preparation by the aid of some aromatics, wine and glycerin, and, with the assurance of the manufacturer that it has taken years of study to perfect the formula, it is at once successfully launched into popular favor among prescribers, and takes the place of old and well known preparations over which the new one possesses no tangible advantage But a more serious manifestation obtrudes itself as a consequence of the modern practice Formerly the physician, confining his prescription to drugs, chemicals and preparations of officially recognized quality and composition, knew exactly what he was prescribing and the patient accepted his prescription without inquiry Now, the patient is familiar with the name or title of the medicament that is being prescribed for him, and is more than likely to ask for it without prescription, while neither he nor the physician has a true knowledge of its composition, for such knowledge is in most instances based upon more or less obscure or misleading statements borne upon the label or upon the circular accompanying the preparation

Under these conditions it is not to be wondered that the purely commercial element has overwhelmingly gained ascendency in the practice of pharmacy and that the professionally inclined are largely in the minority, I was about to say hopelessly so, but I am unwilling to concede that I have occasionally met with the statement that, as applied to politics, the minority is always in the right However this may be of politics, I am not sure that it applies with like force to the revolution that has invaded the practice of pharmacy, but I do believe that, with persistent effort, and with the aid of thinking men in the medical profession, the minority will eventually lead the majority into channels in which the commercial shall be subservient to the scientific and professional qualifications Among these efforts perhaps the most important is the successful introduction of authoritative formulas for the preparations that are now popularly prescribed, and the acceptance by physicians of the preparations made in accordance with such formulas by reputable pharmacists everywhere This has been the aim of the American Pharmaceutical Association in compiling and issuing the "National Formulary," a work which has been completely revised since the date of my paper initially referred to, and which has in some degree at least met with recognition by the medical profession. In fact, in some localities, where its merits have been properly presented to physicians, it has been accepted as authoritative for many preparations to replace those of special manufacture, and as the work becomes better known its usefulness will doubtless be extended. In furtherance of this object, and with the hope that the work may become more generally known and appreciated by prescribers, I therefore venture to again call the attention of the AMERICAN MEDICAL ASSOCIATION to the "National Formulary," illustrating its utility and scope by brief comments on a few preparations that seem to merit attention and to serve as types of the general contents.

---

[1] "The National Formulary" Read by invitation in the Section on Materia Medica and Pharmacy at the Forty fourth Annual Meeting of the American Medical Association

With a list of eighty-six formulas for elixirs, forty-seven for syrups and forty four for liquors, one should consider the ground of modern so called elegant pharmacy pretty well covered but the list utterly falls short of the number which enterprising individuals have succeeded in introducing to the notice of practitioners of medicine, and which must be kept in stock in a modern pharmacy. The difference between the one and another is in many cases that between "tweedle dee and tweedle dum," the selection by the prescriber being quite as much due to convenience or whim, and in neither case justified, when the identical components on the shelves of every properly appointed pharmacy may expeditiously be compounded into a palatable and acceptable preparation. It is true that to construct his own formulas will put the prescriber to some inconvenience! In some cases he will probably be compelled to consult with his neighboring pharmacist so that the resultant prescription may be sightly and palatable as well as efficient. But the trouble is well worth the taking, for his results in the treatment of disease will be based entirely upon his own selection of the medicament instead of, as is too frequently the case, upon that of the manufacturer. If then, the prescription having become established to his satisfaction, the physician will take the trouble to write out the components when prescribing, he can reasonably hope to have his prescription prepared acceptably at any respectable pharmacy, or in case the formula is too lengthy and circumstantial, its publication in some of the numerous medical and pharmaceutical journals will make it public property, as it should be, and the preparation may then be prescribed under a selected title. Unfortunately the practice has gained ground modernly that formulas constructed under the conditions named are being withheld from publicity and a new child is thus born to enrich the modern materia medica, in most instances under a coined name and with the corner druggist as its sponsor.

It would necessitate a far more lengthy paper than is contemplated or useful at this time to go into details concerning the composition of the preparations of the "Formulary," for these details mainly concern the operator to whom the compounding is entrusted. The prescriber, however, should fully understand that the operations involved are in most instances of the simplest character, the formulas are constructed on simple lines, and the directions are given in terse diction and with such precision that the merest tyro, so long as he has the ability to weigh and measure correctly, can follow them to a satisfactory end. It is otherwise, however, when the exigency for a new formula arises, whether it be for the purpose of simply combining an additional medicament with a preparation already made, or whether it be with the object of exhibiting one or more medicinal agents in a more acceptable form. Here a thorough knowledge of compatibles, both in a chemical and physical sense, is necessary, and the opportunity arises for consultation between the prescriber and the pharmacist. Take, for example, Elixir of Ammonium Valerianate (Formula No. 33.). It is important that this should be perfectly neutral or slightly alkalin, so that the odor of valerianic acid may be completely overcome. Properly prepared, it may be combined with any neutral or basic medicament without impairing its quality, but if we were to add an acid substance, the odor of valerian would be immediately developed and the utility of the preparation impaired. Again, the finished preparation may require the presence of a free acid, for example, the Compound Digestive Elixir (Formula No. 59.). This preparation containing both lactic and hydrochloric acid in a free state, it will not do to combine it with basic or alkalin substances, though neutral or acid compounds are perfectly compatible. In other cases the judgment involved may concern the physical character, such as taste and odor only, an example of which is the Compound Cathartic Elixir (Formula No. 45.). In this we have the problem before us to make a palatable preparation from a number of bad-tasting or malodorous drugs, such as senna, mayapple, leptandra, jalap, etc., which is successfully solved by the judicious use of the Elixir of Taraxacum (Formula No. 111) and of Elixir Glycyrrhiza (Formula No. 76). Numerous other examples might be cited, but sufficient has been said to point out how the physician and pharmacist, with the material provided in the "Formulary," may acceptably produce almost any combination that may be desirable.

The "Formulary" also commends itself on the score of economy. Many of the preparations can be made extemporaneously, or at short notice, with such materials as are on the shelves of every well appointed pharmacy, there being only a list of ten preparations—in themselves inexpensive—which for the convenient preparation of the others are advised to be kept in stock. This facility to make palatable preparations at short notice also commends itself on the ground that they will reach the patient in an absolutely fresh condition, and particularly so in the case of two classes of preparations—the "Emulsions" and the "Effervescent Powders." Possibly both of these have had their day, for they are not prescribed with nearly the frequency they were formerly. But for that very reason it is desirable that the pharmacist should be placed in position to dispense them in a fresh condition, since both of these classes of preparation rapidly undergo change and become unfit for use, and being usually dispensed in original containers and under seal, it becomes practically impossible to insure their quality. The "Formulary" makes excellent provision for both. With regard to

Emulsions, it observes that "the successful formation of emulsions, whether of fixed or volatile oils, is most successfully and expeditiously accomplished with acacia as the emulsifying agent." Hence, preference is given to acacia, though other emulsifying agents, such as mucilage of Irish moss, mucilage of dextrin, glycerite of egg and tincture of quillaya, are not ignored, their use and application being exemplified in a number of alternative formulas for preparing Emulsion of Cod Liver Oil. The directions given are so plain and explicit that they may be readily followed by the operator with assurance of the production of an emulsion containing 50 per cent by volume of the oil, together with such other medicinal ingredients, hypophosphites, flavoring, etc , as it may be desirable to incorporate In the case of "Acacia Emulsion" the amount of the acacia need not exceed 12 per cent , while the emulsification is as perfect as in the best emulsions of the market, and far more so than is the case with the most of them Good, pure material is easily obtained in the market, and will certainly be supplied by the pharmacist if the physician will take the trouble to make the demand for the pharmacist's rather than for the manufacturer's product As to

Effervescent powders, the "Formulary" maintains that they are most conveniently and efficiently dispensed in the form of *fine powder*, because in this condition they can be made extemporaneously and with an assurance of their freshness and efficiency The popular demand for "Granular Effervescent Powders," however, is not ignored, and formulas are given for their preparation under modifications which are important only in so far as they enable the dispenser to granulate the powder in a convenient and expeditious manner But the granulation of the powder is admissible only if it is contemplated to prepare the effervescent preparation for stock, and the liability of such to deteriorate on keeping, being the same as that of manufactured effervescents, should prompt the physician to discourage their use, by confining his prescription to extemporaneously prepared effervescents *in fine powder* The latter can be made as quickly as any prescription that requires the admixture of several powders To make the plain (non-medicated) effervescent powder, two stock powders, the one composed of sodium bicarbonate and sugar (Saccharated Sodium Bicarbonate, Formula No 341), the other of tartaric acid and sugar (Saccharated Tartaric Acid, Formula No [illegible]8), are mixed in equal quantities by weight, the proportions of acid to sugar and of alkali to sugar being such that, weight for weight, the two powders represent molecular proportions, and when so mixed form a neutral solution Both of these powders, when made from dry and anhydrous material will keep indefinitely, but may be prepared expeditiously if not in stock The medicinal agent having been weighed and finally pulverized if necessary, with a small portion of the plain effervescent powder, a sufficient quantity of the latter is then incorporated to make four grams for each dose contemplated, and the resultant powder may then be dispensed in bulk, to be given in doses of a teaspoonful, or, better, divided into doses of sixty grains, each dose to be enveloped in wax paper Obviously, any desired medicinal combination of dry, soluble substances can be thus prescribed, a typic prescription being as follows

℞ Citrated caffein 12 gr
Lithium citrate 24 gr
Saccharated tartaric acid (N F)
Saccharated sodium bicarbonate (N F) āā 3 dr
Mix intimately and dispense in twelve equal parts (or in bulk) each enclosed in wax paper

The advantages resulting from the practice of so prescribing are

Accuracy, because the composition is determined by the prescription

Celerity, because the prescription can be prepared from stock at hand, and there is no delay in searching the market for a specialty

Efficiency, because the medicine is freshly prepared

Economy, because the prescription need not exceed a single dose, and there is no loss from deterioration But not the least of the advantages to be gained from this practice is that the physician and pharmacist are kept in touch with each other, instead of—as is inevitably the case under modern practices—drifting asunder

THE PONS ASINORUM OF THERAPEUTICS

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo , June 7 10 1898

BY ROBERT G ECCLES, M D

Member of Committee of Revision of the United States Pharmacopeia 1890-1900 Fellow of the American Association for the Advancement of Science Member of the Scientific Alliance of New York, Member of the American Chemical Society Member of the American Anatomical Association Managing Editor of the American Medico Surgical Bulletin Member of King's County, New York, Medical Society, Member of the American Pharmaceutical Association, Etc
BROOKLYN, N Y

In the fifteenth century one Johannes Buridan published a treatise which he called the *Summula de Dialectica* and set forth to the public that it would enable any person, however stupid, to easily and rapidly discover the "middle terms" for syllogisms On the strength of this claim it came to be known as the *pons asinorum* or bridge for what our Colorado friends call "burros "[1] At a later date the fifth theorem of the first book of Euclid came to bear the same title, and still later the forty-seventh proposition of the same book bore this name because they enabled dull students to master otherwise very difficult problems In modern parlance a *pons asinorum* is a bridge over a mental difficulty that enables ordinary mortals to cross Geniuses can, of course, get over without such aid In using it in therapeutics the writer denies any intention of intimating that there are any members of the medical profession whom he feels justified in cataloging as belonging to the genus *Equus*, species *asinus* We merely use it for the purpose of forcibly indicating the sad need of such a bridge at this point of medical progress Without it we have the choice of resting entirely in a fool's paradise, taking wings and soaring with the geniuses over the muddy stream of ignorance or remaining mental grallatores' floundering in the deep waters of that practically unfordable stream It is not the first time in the history of science that such alternatives have been placed before mankind As a rule the majority prefer to remain within the fool's paradise The subjective method of the metaphysician is much more congenial than the experimental, objective method of getting at truth or what the world considers truth In therapeutics we are all as anxious to discover a law of cure as were the alchemists to discover the elixir of life, but we of the regular school prefer the inductive, slow method of chemistry to the wild dreams of alchemy Any pretended therapeutic law that fails to come down to the bed-rock of cause is a mere hallucination When we can trace by cause and effect exactly how remedies produce their results, then and not till then will we have a true law of cure We are already sufficiently far advanced to see the way in which it is likely to be found and to observe where our pons to it is being built The caissons have already been sunk through the muddy bed of ignorance, and we shall soon see its graceful arch spanning the stream below In this essay the author hopes to be able to show 1 That all effective therapeutic measures are preventive ones, depending almost wholly on our ability to make a correct diagnosis 2 That our present paucity in successful results is due to defective diagnosis 3 That we cannot overcome this defect, so far as the great majority of medical men is concerned, until we are supplied with a binomial or trinomial nomenclature of diseases

The therapeutic bridge we need is a scientific system of naming diseases so that the average medical man will be able to know what he is trying to get rid of by the remedies he uses Our present lack of system is a sad hotchpotch, that if merely useless might be tolerated, but that being positively misleading should be consigned to oblivion as quickly as possible In medical matters we stand today precisely where botanists and zoölogists stood before the immortal work of Linneus was accomplished Our confusion is as great as theirs was and our gain from a similar revolution would be far greater Now is the time for us to inquire "where we are at" and try to get order out of the awful chaos that surrounds us If something is not done soon, we will all be constrained with Cicero to exclaim, "*O dii immortales! ubinam gentium sumus?*" (Ye immortal gods! where in the world are we?)[2]

The number of causes capable of producing bodily ailments is infinite Fortunately there is a natural grouping by which it is possible to place them all in a few convenient classes Some are due to mechanical, some to chemic and some to biologic (usually microbial) injuries If we add to these causes those due to errors of development, we will probably have covered every possible form In consonance with this grouping of causes there can be a corresponding grouping of effects, thus enabling us to have what we are pleased to call distinct diseases There are in reality no such things as distinct diseases Disease in all its protean forms is but the resultant effects of a multitude of causes, being resisted by the organism As effects often mimic each other, it is never possible for us to be absolutely sure of the nature of any disease until we have discovered its exact causes The first step toward a rational course of treatment is the step that leads us toward knowing what we have to treat Until we discover that, what we happen to do is little better than blind guess-work

To make clear our meaning consider for a moment two illustrations Suppose we go home and find our window broken and go in search of the cause of the break It may have been the wind, it may have been a stone, or it may have been any one of a multitude of causes To discover that it was done with a stone does not in any way help us toward a knowledge of how to mend it In cases of this kind a knowledge of the cause of the disease or damage does not help us to a knowledge of the remedy required Now let us change our supposition a little , Instead of a broken window let us choose broken ice on a skating pond Being anxious to see that pond frozen over we look out upon it from time to time on a cold winter's day and each time discover a huge hole at the same point on its surface We go out near it in order to discover the cause and find that it was being pelted with stones No sooner was new ice formed than it was broken again by a large stone being thrown through it To discover the cause in this instance is to discover how to remedy the evil As soon as we stop the stone-throwing the break closes

Here we have a case of cause and effect exactly like those with which physicians have to deal The same class of forces can operate to damage organisms as operate to damage ice, and the process of mending, healing or curing is exactly analogous in both instances Observe here that the mending in the one case and the curing in the other is accomplished by inherent forces All that we can do in either instance is to remove some continuously operating cause or causes and then nature does the rest In the case of the broken ice a cure of the evil occurs when we stop the stone throwing In the case of our patient the cure occurs when we stop the action of the damaging force The ice can cure itself by freezing so fast that between the intervals of stone-throwing it becomes thick enough to resist the blow The body can cure itself if its repairing forces work with sufficient vigor to render nugatory the attacking causes Both the human body and the ice do their own repairing of damage always We can only remove the obstruction and overcome the causes that hinder their inherent activities Whenever any cause interferes with the development of a clear crystal of ice or a pure healthy body that cause must be removed or no cure is possible Sometimes many causes may be at work simultaneously damaging the ice or damaging the body and then all of the morbid causes must be removed before nature can assert herself by a cure At other times different damaging causes may succeed each other, the first, second and third having disappeared and a fourth having come in to keep up the mischief In the case of the ice a succession of stones may have been succeeded by a fire and this again by sulphuric acid All of these may have done their share toward damaging the ice until finally a mass of salt may have been placed upon it To cure the damage it will do no good to remove the spent stones, the extinguished fire or the saturated acid We must know that there is fresh salt there and remove it Thus it is in the body The first injurious cause may have gone when we are using remedies for it It is necessary to know the cause now acting and seek to remove it If we find a person being burnt we can extinguish the flames If we find that acid has been thrown upon him we can stay its ravages by removing it or neutralizing it When there is no longer any fire or acid present we must see that the damaging air does not affect the wound and when this is looked after we turn our attention to the invading bacteria so as to arrest their destructive work

The kind of microbes that invade the wound may have an important bearing upon the healing of the wound To successfully treat each case we must know the kinds that invade it All obstructions to the proper healing of the body must be discovered and a way found for their removal, otherwise we will continually keep failing to cure our patients Where we do not know the causes we can not hope to be always remove them An accidental discov in some cases give us a method, but as a ru grope in the dark until the causes have ered In the majority of such cases we lea ter to nature and then take to ourselves t' doing the work We speak of some remedies as "almost specifics," because they succeed in a large proportion of cases and in a way that leaves no doubt of their efficiency The writer believes that where such remedies fail other causes than the one thought responsible are at the bottom of the failure If we knew how to overcome these unknown causes that lead to failure we would be successful every time When we give quinin in malaria, mercury in syphilis and serums in their respective diseases their failure is due to the presence of causes that they were never intended to treat All successful medication is preventive medication Prophylaxis is the very soul of cure in every form of sickness When we give quinin we kill the plasmodiums and prevent a new attack of the malaria When we give diphtheria antitoxin we produce conditions unfavorable to the Klebs-Loeffler bacillus and so prevent a continued attack of the diphtheria When we give a cathartic we force toxic substances out of the body and prevent auto intoxication When we can not get at the root of a disease we are content to attack and prevent the evil consequences likely to flow from some dangerous symptom By thus being able to, as it were, lop off the tentacles of the disease we often cripple or destroy it as a dangerous enemy of the patient Where sleeplessness is leading toward death, by the use of sulphonal or morphin we prevent this much of the disease from developing We obviate the serious outcome The deeper down our prophylactic measures can be carried among the bad symptoms the more likely are we to save our patients To know how to prevent a tetanic spasm is not as good as to know how to antidote the poison of tetanus but it is well to be able to accomplish the lesser feat when for any reason we can not do the greater There is no breach in continuity between sanitation and treatment The aim and method of the one is the aim and method of the other The method of each is summed up in the one word "prevent" To give drugs for any other purpose than the preventing of untoward effects is foolish Beneficial symptoms should be let alone or encouraged It is therefore important for the physician to be able to tell what symptoms of a disease are beneficial and what damaging Grave blunders are committed by not knowing which to encourage, which to let alone and which to oppose

The one important duty of the physician always is to fight or remove everything that he is sure is leading his patient toward a disastrous termination of the disease He must at all times be on the alert for causes of evil and in their succession the deeper he can go the better will be his results in all kinds of cases Skill in diagnosis is imperative, whether the inquiry relates to a baneful symptom or a specific cause To give remedies that have been recommended for diphtheria, pneumonia, nephritis, mumps or measles because we have concluded that these are the ailments from which our patients suffer may by a sheer lucky hit be what they need, but the chances are very many against us in the matter Superficial diagnosis, that knows no more about these diseases than is implied in the ability to give them these names, is wholly inadequate as an aid to proper treatment Much more must be known, and the idea that disease is an entity, which our present nomenclature fosters, must be destroyed An examination of the present trend of bacteriologic discovery will help us to a clearer conception of what is here meant and perhaps illuminate the subject in a number of important directions

Let us for a moment consider the bearings of the fact that adaptation is a fundamental law of life A study of the distribution of plants and animals throughout the globe shows us that the leading factor in placing them where we find them has been fitness Water plants and water animals can not live in dry places while plants and animals able to live in dry places can not, as a rule, thrive well in wet places The same is true for extremes of heat and cold, richness and poverty of soil, sunlight and shade, windiness and calm, with all other extremes of telluric conditions Between the extremes of adaptation are all possible intermediate degrees The range, too, of all plants and animals varies widely in extent in every environment Some have a very wide range and others are restricted What is true of the gross fauna and flora of the earth is equally true of the microscopic The latter, like the former, develop vigorously where adapted, not at all where wholly unadapted and with intermediate degrees of vigor amid intermediate degrees of fitness Microbes that are classed as non pathogenic are such as are unable to spread to a damaging degree within the tissues of the body or such as are unable to produce poisonous substances within the body to its detriment Pathogenic microbes produce poisonous substances or multiply within the body in a way that is injurious to it They bear a similar relation to the body that weeds do to a garden While there may be parts of the body that can resist their development, other parts are more favorable to them, permitting of their development A given microbe may be able to develop in the lungs but not in the spleen Another may find a favorable place of development in certain glands but be unable to multiply in the meninges To some extent there is certainly reason to believe that most tissues have some degree of protection from some forms of disease germs To hold, however, as many have done in the past and as some seem to do now, that but one kind of disease microbe is capable of developing in the kidneys, another in the brain, another in the spleen, another in the liver, another in the bones, another in the heart, another in the lungs, etc, seems extremely absurd

The final settlement of the question regarding which microbes are capable of developing to a dangerous extent in the lungs and which in the liver or other organ must be arrived at by actual experiment Analogy and probability seem now to lead to the conclusion that there are many pathogenic microbes capable of development in dangerous numbers in any one of all the tissues and organs of the body if they can only gain access to the same in any manner It does not seem reasonable to think that nature should have given a monopoly of the lungs to some one kind of coccus, of Peyer's patches to a single kind of bacillus or of the liver or intestines to a single kind of spirillum It is much more reasonable to believe that soil that will grow one kind of plant is likely to be able to grow many kinds It would, indeed, be a singular plot of ground that, while containing many patches of differing soils, could only grow one solitary kind of plant on each kind of soil Imagine if you can such a plot In it the potato corner could grow neither peas, onions, weeds nor other plants, the pea patch could grow nothing but peas, and the onion region would be an inhospitable home for anything but onions Is not such a supposition absurd on its face, and yet it is no more absurd than the assumption that meningitis is due to but one kind of microbe which by diligent search is going to be discovered some day. Is it not much more reasonable to think that there are twenty or more kinds of germs capable of producing meningitis? To us it would not be at all surprising if future investigation should show that there are twenty or more kinds of pneumonia, hepatitis, meningitis, cystitis, enteritis, tonsillitis, carditis, gastritis, nephritis, etc. Is it not also quite reasonable to suppose that the cause of the pathologic condition in any one of these may be the cause in many of them? In other words, may not the nephritis of one patient have the same specific cause as the meningitis of another, the pneumonia of another and the carditis of another? If more than one kind can develop in the same region at the same time may not two or more kinds of microbes combine at various times to produce conditions of disease very like those produced by only one? Again, as microbes are known to have a sort of succession among themselves, may it not be possible that in some diseases the latter symptoms are due to a different set of germs from those at the beginning? All of these questions can only be finally answered by an appeal to nature.

Now let us inquire about the facts in the case as developed by bacteriologic investigation up to the present time. Dr. Kanthack, the pathologist of St. Bartholomew's Hospital, London, in Allbut's System of Medicine says that "undoubtedly the same morbid lesion may be produced by several different micro-organisms." "Strictly speaking, then, there is no specific organism of infective endocarditis; any one of a number of cocci may produce a disease, bacteriologically different from, but anatomically, pathologically and clinically identical with that produced by another member of the same group of organisms. Similarly, suppuration may be produced by any one of a large number of bacteria, and in the malady clinically recognized as erysipelas, instead of the streptococcus of erysipelas, other organisms may often be found. Septicemia and pyemia, again, may be produced by more than one kind of bacterium, and the same applies to pneumonia."[3] To these words there is no uncertain sound, although the author of them still clings to the belief that some kinds of germs are specific. It is always in regions of ignorance that old expiring notions take their final refuge. There are diseases of which we know little that may appear to possess the old quality known as specific and that we will have to consider such till we know more about them. Phthisis pulmonalis was at one time deemed a specific disease, but Koch's discovery of the tubercle bacillus showed it to be but a single form of tuberculosis. We now know that there is tuberculosis of the lungs, tuberculosis of the brain, tuberculosis of the skin, tuberculosis of the bones, and tuberculosis of almost every part of the body. If we consider the group of symptoms, including the lesions, as the disease then there can be no such specific disease as tuberculosis. It is only by claiming that the presence of the bacillus gives it a specific character that we are able to maintain such a position, but that would make every disease specific in a similar sense.

Dr. S. Flexner tells us that phthisis pulmonalis, or a disease with all of its symptoms, exists, in which there are no tubercle bacilli. In it we find a streptothrix instead.[4] Prof. Edgar M. Crookshank has pointed out that many of the lesions of actinomycosis and those of tuberculosis are alike.[5] Dr. Karowski of Berlin says the early stages of actinomycosis and of tuberculous phthisis require a bacteriologic examination to be sure of their difference.[6] Dr. A. Gouget reports a pseudo tuberculosis of the spleen, liver, kidneys and other organs due to a streptobacillus and not to Koch's bacillus.[7] On the other hand, Dr. J. W. Moore tells us that the tubercle bacillus can cause pneumonia.[8] With this last named, so called disease we have abundant evidence to show that it has a multitude of causes. In the paper of Dr. Moore we learn that pneumonia is caused by the microbes of erysipelas, influenza, typhoid fever, tuberculosis, diphtheria and anthrax. Dr. Peter of Paris sustains this claim of there being an erysipelas of the lungs that we class as pneumonia.[9] Drs. Flexner and Anderson have also shown that diphtheria of the lungs is a pneumonia.[10] Wright and Stokes reported that in nineteen cases of bronchopneumonia the diphtheria bacillus was present.[11] Constanzo Zenoni reports cases of pneumonia due to a streptococcus.[12] Flugge gives Friedlander's bacillus as a common cause of pneumonia.[13] Dr. Moore gives evidence that typhoid fever of the lungs is pneumonia. He holds that in such cases the bacillus of Eberth gains entrance through the lungs as the initial lesion of the disease.[14] Whitelegge tells us that Friedlander's micrococcus, Fraenkel's diplococcus and Klein's bacillus have all been, on apparently conclusive evidence, established as causes of pneumonia.[15] Palamidessi *of Florence reports* cases of pneumonia from a micro-organism resembling those of fowl cholera and which was imported with parrots.[16]

It is apparent from the evidence now in our possession that typhoid fever is as protean in its forms as is tuberculosis or pneumonia. A number of cases have been studied that give evidence of the power of the typhoid germ to attack the body through various channels when there are no evidences of intestinal lesions. Dr. Keen reports cases of meningitis, pleurisy, goiter, hepatitis, pneumonia, and other affections occurring as sequels of typhoid fever, and others as occurring when there were no typhoid lesions in the intestines, but the typhoid germs were present in the organs affected.[17] An editorial note in the *Medical Press* reports five cases of typhoid infection without typhoid lesions.[18] Dr. Taty describes a case of melancholia with mental alienation of a double form due to typhoid germs.[19] Drs. Flexner and Harris describe experiments and cases of typhoid infection without typhoid lesions.[20] These authors also quote the evidence of DuCazal,[21] Kühnau,[22] Guinon,[23] Pick,[24] and especially Chiari and Krous,[25] as bearing in the same direction. Keen mentions the fact that pure typhoid cultures have been prepared from points of suppuration in many parts of the body.[26] The same author refers to cases of mumps as due to the typhoid infection[27] and of diseases of the bones as having the same cause.[28] Gasser describes a case of orchitis due to typhoid infection,[29] and Girode gives evidence of epididymitis having occurred from the same cause.[30] DuCazal and others have secured pure cultures of the typhoid bacillus from the spleen when there were no intestinal lesions.[31] In this connection it is interesting to learn that in a case of Dr. R. D. Mason's where the patient had swallowed some lemon seeds an[illegible] sprouted in the intestines, the sy[illegible] were like those of typhoid fever.[32] [illegible] that other things than the typhoid ge[illegible] characteristic symptoms of typhoid fever, and that the typhoid germs sometimes produce symptoms not at all characteristic of typhoid fever as usually recognized.

If we turn next to as apparently specific a disease as gonorrhea, every physician knows the danger to the eyes of the newborn by infection with the coccus of this filthy affection, and now Dr. F. R. Hagner tells us that he has found cases of arthritis and tenosynovitis giving cultures of gonococcus.[33] In catarrhal conjunctivitis Dr. Gifford found that in an epidemic in Omaha, Neb., and surrounding country Fraenkel's pneumococcus was the cause, while in another in New York which he had had experience with a wholly different microbe was the cause.[34]

The discovery of the Klebs-Löffler bacillus and the study of its characteristics have within a short time completely altered our conceptions concerning diphtheria. Now there are cases, which a few years ago would not have been considered as even related to diphtheria, that are classed with that disease, and a number of anginal affections that we called diphtheria are now excluded from such recognition.[35] Dr. W. P. Herringham of St. Bartholomew's Hospital, London, says that "it must be remembered that membranes, produced by other bacteria besides the diphtheria bacilli, may appear in the throat, and that in many cases the clinical phenomena prove to be of but little assistance, a careful bacteriologic examination is therefore required."[36] Anders tells us that "diphtheria may exhibit a number of variations as regards the seat of attack and the severity of the poisoning." He mentions nasal diphtheria, wound diphtheria of lips, tongue, vulva or glans penis, laryngeal diphtheria, etc.[37] S. Gee refers to latent diphtheria, in which the poisoning occurs without the appearance of a membrane of any kind.[38]

Turning now to meningitis, we learn from the last report of the Massachusetts State Board of Health that in ten cases examined they found it due to the pneumococcus, in eight cases to streptococcus, in twelve cases to tubercle bacilli and in one case to anthrax.[39] Dr. J. A. Ormerod says that in some cases of purulent meningitis there has been found a micrococcus, in others the ordinary streptococcus pyogenes, and where the meningitis occurs "in connection with some acute infectious disease, such as typhoid, the organism proper to that disease."[40] If we next consider endocarditis we find the same state of affairs. Dr. Julius Dreschfeld, Professor of Medicine in Owens College, Victoria University, tells us that in most cases of this disease only one kind of organism was found in each case, but that they vary in kind for different cases. The organisms that have been found in this disease have been in some cases streptococcus pyogenes, in others streptococcus of erysipelas, in still others staphylococcus pyogenes aureus, and thus through different cases were found the pneumococcus of Fraenkel, the pneumobacillus of Friedlander, the typhoid bacillus, the bacillus of tuberculosis, the bacillus of diphtheria, the gonococcus, the bacillus endocarditis griseus, the micrococcus endocarditis rugatus, the bacillus endocarditis capsulatus, the bacillus immobilis et fœtidus, the bacillus of Gilbert and Lion, and a few other microbes with less definite character.[41]

Some of the names in this formidable list indicate the discoverer's idea that there was but one microbe of endocarditis. This antiquated notion is a vestige of demonology, which taught that every disease was an entity due to one simple cause, and that cause a demon or ghost obsessing the patient. The deeper we study the more clear the evidence becomes that no absolute specific character belongs to any disease. Many causes can produce symptoms in common, and as the sums of symptoms constitute the disease, we may expect to find no lines of demarcation in which disease does not merge with disease. There are specific causes for every diseased condition and the knowledge of these causes is what we need, to be able to treat them successfully. Dr. Stephen Mackenzie, in his presidential address in the Section of Medicine of the British Medical Association, at its Montreal meeting, expressed this idea in the following words: "Until the exact nature of disease is fully understood, a truly scientific treatment is manifestly impossible."[42] But now the question arises as to how we are going to reach an exact knowledge of diseases as long as we continue using a nomenclature that is a source of daily deception and misunderstanding? Nomenclature is the mental tool of every diagnosis. Imagine our trying to study botany without our present nomenclature. Professor Allbutt of the University of Cambridge in the introduction to his "System of Medicine" has, we are quite certain, made the one error of that ably edited set of volumes when he throws the weight of his great influence against the naming of diseases by a system of nomenclature analagous to that used in botany and zoölogy.[43] Does he propose to have us forever remain without names to indicate those "groups of certain degrees of constancy" among symptoms? If the grouping and exciting causes are united in a double or triple name all of Professor Allbutt's objections disappear at once. We are already drifting naturally toward it. We can not avoid it if we desire to. No man is strong enough to stay the current for very long. Any system of naming diseases by a single name will perpetuate the wholly false notion that a disease is a something like an entity. The single name and the demon notion were conceived together and will by association always suggest something of each other. A new system that would not only do away with that suggestive association, but that would also force the mind toward a knowledge of the congeries of symptoms would check the very tendency which Dr. Allbutt fears. In the names "typhoid pneumonia" and "tuberculous meningitis" we have already developed the germ of a truly scientific nomenclature. Let us agree to make the existing cause or causes, as soon as known, the generic name of the disease and the lesion or primary seat of the infection the specific name. As our knowledge grows more profound we will be able to group the causes into families if we desire to do so, but at present it is unnecessary.

It is a pity that our bacteriologists have not yet discovered the specific causes of such common diseases as measles, scarlet fever and smallpox. They should have been among the first properly named, but as it is they could only be named provisionally. As soon as we hear of diphtheria pneumonitis, typhoid pneumonitis, erysipelous pneumonitis, streptococcus pneumonitis, diplococcus pneumonitis, etc., we naturally form a mental image of an inflammation of the lungs due to the general cause which the generic title indicates.

With a pliable nomenclature such as this we can have not only diphtheria or diphtheritic pneumonitis, but we can have diphtheritic meningitis, diphtheritic hepatitis, diphtheritic cystitis, diphtheritic nephritis, diphtheritic carditis, diphtheritic enteritis, etc In the same manner we can have with typhoid pneumonitis all such combinations as typhoid meningitis, typhoid cystitis, typhoid enteritis, typhoid hepatitis, typhoid gastritis, typhoid carditis, typhoid nephritis, etc Should we discover that in some form of typhoid infection the skin was the chief lesion, we would call it typhoid dermitis, and if the blood should be found the chief seat of the disease we could call it typhoid hemocytolysis In case there is no particular localization of the damage, a general name could be supplied to express this idea, and where two, three or more distinct points of infection exist simultaneously this too could be expressed in a name Where the specific microbe has a double or triple name these would have to be united and shortened, about as chemists shorten long organic chemic names Amœba coli enteritis might be shortened into the name amcol enteritis In this way the binominal system could be maintained for all ordinary affections and a trinominal kept for varieties We already know that there are varieties of cholera answering to various kinds of spirilla and varieties of malarial affections due to different kinds of plasmodia In such cases a triple naming would be a better means of telling the cause As soon as such a system of naming diseases has become current it is but a short step to a corresponding system of analysis as applied to symptoms for the discovery of causes

No effort has ever yet been made to classify symptoms in a scientific manner so as to aid the physician in making his inductions As there is really but one disease, varying with the cause or causes and with the extent and location of the lesions, symptoms naturally arrange themselves in interblending groups There are symptoms common to every disease, symptoms common to large groups of related diseases, symptoms common to small groups of diseases, and symptoms that belong to a single disease Without a proper system of naming diseases their proper groupings is impossible Correct the former and we can soon have the latter With a proper nomenclature we can soon tabulate the symptoms as they appear First we can find the most general ones that every form of disease manifests as soon as it has reached a certain degree of intensity Next we can get a list of the symptoms common to the large groups, then to the small ones and finally to the single ones The last-named symptoms, if correctly gathered, will tell the exciting cause, and when it is found, treatment is simplified to its utmost

POTASSIUM IODID IN CEREBRO-SPINAL MENINGITIS

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo , June 7-10 1898

BY H A MOODY M D

MOBILE ALA

The object of this brief paper is to emphasize the value of potassium iodid in meningitis, especially in that severe and fatal form known as cerebro-spinal meningitis

Since deciding to present this subject I have looked through quite a number of the authorities most frequently consulted by the general practitioner, to form an approximate estimate of the appreciation in which this drug is held in the treatment of meningitis I find that its use is recommended by many of them, but seldom during the stage in which I have found it most efficient Biddle does not mention it in this connection, neither does Hare in his shorter work, the one most frequently consulted Potter recommends a longer course of it during convalescence Wood does not recommend it, neither does Stillé Bartholow recommends it to remove adventitious products after the acute attack has subsided Skinner reports Dr Valten as asserting that it acts almost as a specific in epidemic cerebro-spinal meningitis Flint says that symptoms of oppression call for potassium iodid Von Ziemssen states that in a later period of the disease it is of great service Osler merely remarks that iodid of potassium is warmly recommended by some authors Aitken says, "no real proof of its utility has yet been brought forward" From the above it will be seen that we are not much encouraged to employ it by those authors most frequently consulted by the general practitioner

Thirty years ago Tanner said "With regard to medicines directly modifying the morbid action I know only of one in which the least reliance can be placed—the iodid of potassium" My own experience in the treatment of meningitis leads me to endorse the position of Dr Tanner I have witnessed two epidemics of cerebro spinal meningitis, in the first of which the iodid was not used to any efficient extent, while in the second it was the principal element in the treatment

In the first epidemic the treatment was purgation, morphin, chloral, the bromids, ergot, blistering and venesection Nearly all the patients died, some in a few hours, others after many weeks of suffering Venesection received the credit of saving a few lives, but as a rule both doctor and patient lacked the courage to employ it with sufficient boldness for efficiency In the protracted cases the iodid was used to promote absorption, but seldom proved effectual characteristic symptoms of typhoid fever, and that the typhoid germs sometimes produce symptoms not at all characteristic of typhoid fever as usually recognized

If we turn next to as apparently specific a disease as gonorrhea, every physician knows the danger to the eyes of the newborn by infection with the coccus of this filthy affection, and now Dr F R Hagner tells us that he has found cases of arthritis and tenosynovitis giving cultures of gonococcus[33] In catarrhal conjunctivitis Dr Gifford found that in an epidemic in Omaha, Neb, and surrounding country Fraenkel's pneumococcus was the cause, while in another in New York which he had had experience with a wholly different microbe was the cause[34]

The discovery of the Klebs-Löffler bacillus and the study of its characteristics have within a short time completely altered our conceptions concerning diphtheria Now there are cases, which a few years ago would not have been considered as even related to diphtheria, that are classed with that disease, and a number of anginal affections that we called diphtheria are now excluded from such recognition[35] Dr W P Herringham of St Bartholomew's Hospital, London, says that "it must be remembered that membranes, produced by other bacteria besides the diphtheria bacilli, may appear in the throat, and that in many cases the clinical phenomena prove to be of but little assistance, a careful bacteriologic examination is therefore required"[36] Anders tells us that "diphtheria may exhibit a number of variations as regards the seat of attack and the severity of the poisoning" He mentions nasal diphtheria, wound diphtheria of lips, tongue, vulva or glans penis, laryngeal diphtheria, etc[37] S Gee refers to latent diphtheria, in which the poisoning occurs without the appearance of a membrane of any kind[38]

Turning now to meningitis, we learn from the last report of the Massachusetts State Board of Health that in ten cases examined they found it due to the pneumococcus, in eight cases to streptococcus, in twelve cases to tubercle bacilli and in one case to anthrax[39] *Dr J A Ormerod says that in some cases* of purulent meningitis there has been found a micrococcus, *in others the ordinary* streptococcus pyogenes, and where the meningitis *occurs* "in connection with some *acute* infectious disease, such as typhoid, the organism proper to that disease"[40] If we next consider endocarditis we find the same state of affairs Dr Julius Dreschfeld, Professor of Medicine in Owens College, Victoria University, tells us that in most cases of this disease only one kind of organism was found in each case, but that they vary in kind for different cases The organisms that have been found in this disease have been in some cases streptococcus pyogenes, in others streptococcus of erysipelas, in still others staphylococcus pyogenes aureus, and thus through different cases were found the pneumococcus of Fraenkel, the pneumobacillus of Friedlander, the typhoid bacillus, the bacillus of tuberculosis, the bacillus of diphtheria, the gonococcus, the bacillus endocarditis griseus, the micrococcus endocarditis rugatus, the bacillus endocarditis capsulatus, the bacillus immobilis et fœtidus, the bacillus of Gilbert and Lion, and a few other microbes with less definite character[41]

Some of the names in this formidable list indicate the discoverer's idea that there was but one microbe of endocarditis This antiquated notion is a vestige of demonology, which taught that every disease was an entity due to one simple cause, and that cause a demon or ghost obsessing the patient The deeper we study the more clear the evidence becomes that no absolute specific character belongs to any disease Many causes can produce symptoms in common, and as the sums of symptoms constitute the disease, we may expect to find no lines of demarcation in which disease does not merge with disease There are specific causes for every diseased condition and the knowledge of these causes is what we need, to be able to treat them successfully Dr Stephen Mackenzie, in his presidential address in the Section of Medicine of the British Medical Association, at its Montreal meeting, expressed this idea in the following words "Until the exact nature of disease is fully understood, a truly scientific treatment is manifestly impossible"[42] But now the question arises as to how we are going to reach an exact knowledge of diseases as long as we continue using a nomenclature that is a source of daily deception and misunderstanding? Nomenclature is the mental tool of every diagnosis Imagine our trying to study botany without our present nomenclature Professor Allbutt of the University of Cambridge in the introduction to his "System of Medicine" has, we are quite certain, made the one error of that ably edited set of volumes when he throws the weight of his great influence against the naming of diseases by a system of nomenclature analagous to that used in botany and zoölogy[43] Does he propose to have us forever remain without names to indicate those "groups of certain degrees of constancy" among symptoms? If the grouping and exciting causes are united in a double or triple name all of Professor Allbutt's objections disappear at once We are already drifting naturally toward it We can not avoid it if we desire to No man is strong enough to stay the current for very long Any system of naming diseases by a single name will perpetuate the wholly false notion that a disease is a something like an entity The single name and the demon notion were conceived together and will by association always suggest something of each other A new system that would not only do away with that suggestive association, but that would also force the mind toward a knowledge of the congeries of symptoms would check the very tendency which Dr Allbutt fears In the names "typhoid pneumonia" and "tuberculous meningitis" we have already developed the germ of a truly scientific nomenclature Let us agree to make the existing cause or causes, as soon as known, the generic name of the disease and the lesion or primary seat of the infection the specific name As our knowledge grows more profound we will be able to group the causes into families if we desire to do so, but at present it is unnecessary

It is a pity that our bacteriologists have *not* yet discovered the specific causes of such *common* diseases as measles, scarlet fever and smallpox They should have been among the first properly named, but as it is they could only be named provisionally As soon as we hear of diphtheria pneumonitis, typhoid pneumonitis, erysipelous pneumonitis, streptococcus pneumonitis, diplococcus pneumonitis, etc, we naturally form a mental image of an inflammation of the lungs due to the general cause which the generic title indicates

With a pliable nomenclature such as this we can have not only diphtheria or diphtheritic pneumonitis, but we can have diphtheritic meningitis, diphtheritic hepatitis, diphtheritic cystitis, diphtheritic nephritis, diphtheritic carditis, diphtheritic enteritis, etc In the same manner we can have with typhoid pneumonitis all such combinations as typhoid meningitis, typhoid cystitis, typhoid enteritis, typhoid hepatitis, typhoid gastritis, typhoid carditis, typhoid nephritis, etc Should we discover that in some form of typhoid infection the skin was the chief lesion, we would call it typhoid dermitis, and if the blood should be found the chief seat of the disease we could call it typhoid hemocytolysis In case there is no particular localization of the damage, a general name could be supplied to express this idea, and where two, three or more distinct points of infection exist simultaneously this too could be expressed in a name Where the specific microbe has a double or triple name these would have to be united and shortened, about as chemists shorten long organic chemic names Amœba coli enteritis might be shortened into the name amcol enteritis In this way the binominal system could be maintained for all ordinary affections and a trinominal kept for varieties We already know that there are varieties of cholera answering to various kinds of spirilla and varieties of malarial affections due to different kinds of plasmodia In such cases a triple naming would be a better means of telling the cause As soon as such a system of naming diseases has become current it is but a short step to a corresponding system of analysis as applied to symptoms for the discovery of causes

POTASSIUM IODID IN CEREBRO-SPINAL MENINGITIS

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY H A MOODY M D
MOBILE ALA

The object of this brief paper is to emphasize the value of potassium iodid in meningitis, especially in that severe and fatal form known as cerebro-spinal meningitis

Since deciding to present this subject I have looked through quite a number of the authorities most frequently consulted by the general practitioner, to form an approximate estimate of the appreciation in which this drug is held in the treatment of meningitis I find that its use is recommended by many of them, but seldom during the stage in which I have found it most efficient Biddle does not mention it in this connection, neither does Hare in his shorter work, the one most frequently consulted Potter recommends a longer course of it during convalescence Wood does not recommend it, neither does Stillé Bartholow recommends it to remove adventitious products after the acute attack has subsided Skinner reports Dr Valten as asserting that it acts almost as a specific in epidemic cerebro-spinal meningitis Flint says that symptoms of oppression call for potassium iodid Von Ziemssen states that in a later period of the disease it is of great service Osler merely remarks that iodid of potassium is warmly recommended by some authors Aitken says, "no real proof of its utility has yet been brought forward" From the above it will be seen that we are not much encouraged to employ it by those authors most frequently consulted by the general practitioner

Thirty years ago Tanner said "With regard to medicines directly modifying the morbid action I know only of one in which the least reliance can be placed—the iodid of potassium " My own experience in the treatment of meningitis leads me to endorse the position of Dr Tanner I have witnessed two epidemics of cerebro spinal meningitis, in the first of which the iodid was not used to any efficient extent, while in the second it was the principal element in the treatment

In the first epidemic the treatment was purgation, morphin, chloral, the bromids, ergot, blistering and venesection Nearly all the patients died, some in a few hours, others after many weeks of suffering Venesection received the credit of saving a few lives, but as a rule both doctor and patient lacked the courage to employ it with sufficient boldness for efficiency In the protracted cases the iodid was used to promote absorption, but seldom proved effe

Ten years later I was called to visit another community stricken with cerebro-spinal meningitis. To illustrate the violence of the epidemic, I will briefly relate its history. It originated in the home of a farmer whose house was a log cabin containing two rooms with an open passage-way between and a detached kitchen. It was built on low, damp, alluvial soil, and was much too close to the ground for the ventilation needed in southern climates. The family consisted of a man, his wife, and five children aged from 8 to 18 years. Water was procured from a well near the house, and the earth was so wet from spring rains that the water could be dipped out at the top of the well with a dipper made from a gourd. The man told me that before his family was attacked he noticed that some half-grown hogs running loose about the premises acted as though they were sick. He said that some of them "took fits and died."

His youngest boy, abut 10 years old, was taken with severe pain in his head, back and limbs. The physician who was called to attend him noticed a peculiar flea-bitten appearance on the wrists and chest. He suspected some eruptive disease, but the absence of any considerable rise of temperature puzzled him. The patient soon became comatose, and on the second day of his illness he died. Immediately after his death his mother was stricken and on the following day a brother and a sister developed the same symptoms. The physician became alarmed and sent for me to assist him.

I found the mother dead. The two living cases were suffering with severe pains in the head and back. Any touch upon the limbs provoked shooting pains, temperature but little over 100, pulse very soft and compressible, but regular and slow, there was a peculiarly soft, watery look of the eyes, as though there was lack of tension. There was a rose colored eruption, thickest on the wrists and arms, but present in varying degrees all over the body. The spots varied in size from that of a pin-point to a fourth of an inch in diameter. They were evidently extravasations. Upon examining the body of the dead mother I found them much larger and darker than on the living, but the doctor informed me that until her death the spots had been rose colored. I learned that in three other families living near by the same disease had appeared that morning. Each of these new cases occurred in persons who had spent a night or two in waiting on those first attacked. I visited all the cases, and could not doubt the existence of that most terrible of diseases, epidemic cerebro-spinal meningitis. Many kind-hearted neighbors had assembled to help the afflicted family, but when the dreaded name, "spotted fever," began to be whispered among them all left the place except some five or six men who deemed it their duty to bury the dead and remove the survivors from the infected locality. There was a general stampede from the neighborhood, and it is interesting to note that although the disease developed in some of the fugitives it was not communicated to those among whom they had come. Extreme caution, however, was exercised to prevent any unnecessary communication with those who had been exposed.

Remembering the unsatisfactory results of the treatment employed in my previous experience, I decided to give the iodid of potassium a thorough trial as recommended so highly by Tanner. The adults were given from 6 to 10 grains every two hours, children receiving proportionate doses. Pain was controlled by morphin hypodermically administered, and ergotin was also given. Each case had a cantharidal blister on the occiput and the back of the neck. Light was almost excluded, as a matter of comfort and protection to the eyes, and liquid nourishment was given in small quantities.

The number of cases thus treated under my observation was ten, and other cases which I did not see were similarly conducted. One of the early cases, far advanced before recognized, died. There was no further mortality, the disease seemed to yield visibly as the patients came under the influence of the iodid. Few of them recovered without some permanent injury. Several had the sight of one eye destroyed by suppurative choroiditis. Some lost their sense of hearing. In one case there was paralysis of a limb. I attribute the preservation of life to the iodid, because the ergot, morphin and blisters had utterly failed in my previous experience. During the subsidence of the epidemic another case died in a town six miles or more from the point where it originated. How the disease was contracted is unknown, as there was no traceable communication with infected persons or places. The nature of the case was not recognized by the physician for several days. The treatment was first calomel and then quinin, then morphin, chloral and bromids. I saw the case a few hours before death, there was no eruption, but otherwise the symptoms were well marked.

Since the experience above related I have tested the usefulness of potassium iodid in quite a number of cases of sporadic meningitis, and my confidence in its utility increases with experience. Quite recently I administered 50 grains a day for six days to a child 18 months old. Its father is a thoroughly equipped physician. He agrees with me that the iodid was the first medicine to exert any appreciable influence over the morbid process. The child recovered with the loss of its sense of hearing.

INFLUENCE OF AGE IN CAUSING OPACITY OF THE CRYSTALLINE LENS, AND THE PROPER USE OF THE WORD "CATARACT"

Presented to the Section on Ophthalmology, at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY EDWARD JACKSON, A.M., M.D.
EMERITUS PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC; FORMERLY SURGEON TO WILLS' EYE HOSPITAL.
PHILADELPHIA, PA.

The subject of the pathology of cataract is too extensive to be profitably considered in the time at our disposal for the purpose, I shall, therefore, confine myself to one or two phases of the influences which determine opacity of the crystalline lens.

The common use of the phrase "senile cataract" argues a general consent in the view that advanced age has some fixed relation to the condition. That it can not be a necessary, or the only causative factor is demonstrated by the large number of young persons that we see with opacity of the crystalline lens, and by the other fact that many reach even an advanced age without suffering from such opacity.

Of recent years much attention has been directed to certain other probable or possible factors. Among these there can be little doubt but that eye strain exerts an important influence. Many times where there had been recent impairment of vision, and upon examination lens opacity found to be the cause of it with the cessation of eye strain the progress of the opacity has been absolutely checked In a few, not only has the opacity ceased to increase, but there has been noticeable diminution of it Such an occurrence is probably not very rare

It has doubtless happened also to all of us to have encountered cases of lens opacity that have followed acute disease The most striking cases of the sort that I have seen have been in connection with the grippe or epidemic influenza In one of these cases three successive attacks of grippe in three different years were each followed by very rapid increase in lens opacity After the first two there was slow improvement until the patient regained useful vision The third attack left the vision reduced to the perception of moving objects, rendering extraction necessary

With regard to renal disease as a cause of cataract, my experience would indicate that it was not very important The routine of examination of the urine before cataract extraction has shown a comparatively small proportion of cases suffering from albuminuria, or showing casts Angeiosclerosis usually attended with occasional traces of albumin in the urine is quite common among people old enough to be especially liable to cataract And contrary to what I had before supposed, a recent examination of the history of a series of cataract cases has not seemed to support the view that albuminuria was especially frequent

The matter of surprise to me was that this study of the subject showed such great frequency of lens opacity in advanced age The statistics of an ophthalmologist's practice can not always be regarded as reflecting the frequency of certain conditions throughout the community, and yet, it seems to me, that even in that direction the following statistics have some significance, since a large proportion of the patients did not come for the opacity of the crystalline lens, but for other conditions, as acute or chronic conjunctivitis, or the fitting of glasses

Among 10,000 patients attending my clinical services at the Philadelphia Polyclinic and the Wills' Eye Hospital, all of whom were examined ophthalmoscopically, except those in whom the use of the ophthalmoscope was impossible by reason of opaque media, or closure of the lids, there were 1544 over 50 years of age Arranging these by five-year periods I find

Age	Lens clear	Some lens opacity	Totals	Percentage of opacity
50 to 55	460	81	541	15
55 to 60	260	50	310	16 1
60 to 65	196	85	281	30 2
65 to 70	99	83	182	45 6
70 to 75	60	71	131	54 2
Upward of 75	23	77	100	77
Totals	1098	449	1545	29

These figures, especially the percentages, strikingly point toward the importance of age in the production of cataract Yet if we take an affection like toxic amblyopia, especially varieties caused by the abuse of tobacco and alcohol, and arrange the statistics in similar age periods up to the age of 60, the influence of age is quite as striking Thus the age of twenty successive patients affected with toxic amblyopia, arranged in ten-year periods was as follows

Under 30	none in 4627
30 to 40	3 in 2116
40 to 50	8 in 1412
50 to 60	4 in 851
Above 60	5 in 696

Yet we hardly think of toxic amblyopia as due to age So with senile cataract While age is certainly a very important factor, it probably for many cases only constitutes a predisposing cause Before the age of 50 cataract, aside from the result of traumatism, is rare even at that age and for some years afterward, the cases giving a history of injury constitute a rather large proportion

It has seemed to me that at this time eye strain produces a decided effect in increasing the number of cases of lens opacity, since just before that age all patients suffer some strain from their loss of accommodation The history of individual cases points still more strongly in this direction, many times it includes the rapid increase of the opacity during the period of severe strain from presbyopia, and after that the opacity becomes entirely stationary and remains so under proper supervision of the eyes for years

Strain of the eyes from presbyopia is one way in which age may predispose to cataract It is possible that later, in quite an opposite direction, the same influence may be exerted The connection of cataract with choroidal disease and myopia is one of the few established points of its pathology Now, the senile and the myopic eye have this in common that there is less use of normal accommodation and whatever influence it may exert upon the nutrition of the eye is to that extent lost It is certain that myopic and senile eyes show the same tendency to thinning of the choroid and loss of the retinal pigment layer, and it seems not unlikely that intermittent accommodation has some influence in maintaining the nutrition of the lens There is besides these specific influences the general failure of nutrition that occurs in old age and it is not surprising that transparency, a highly specialized character, should be lost simply through the general lowering of nutritive activity

But these statistics suggest another important thought Of patients upward of 75 years of age, 77 per cent show some opacity of the lens Are all such patients to be informed that they are suffering from cataract?

Gould's Dictionary gives as the definition of cataract "Diminished transparency or opacity of the crystalline lens, or of its capsule" This is substantially the definition given in other works of reference But cataract, to the general public, means a disease of the eye leading to blindness, and only curable by a capital operation So long as this c was not discoverable until it had caused g t of vision and was perhaps approaching i for operation, the discrepancy was t now that we recognize the first beg y, in the crystalline lens, the use of the to indicate slight opacities, when it stood to mean early and complete b ously misleading The introduction "incipient cataract" is doubtless in this difficulty, but it does it very imp any phrase that retains the objec Many people have been rendered sk honesty of the surgeon by a diagno which has not after many years, b blindness or any serious impairment have been rendered extremely n blindness from which they were suffer There has even been sc thought in the profession upon the s heard a surgeon announce in a State medical society that he favored operation on cataract in all cases when the vision fell to 20/70 I have known a surgeon of respectable antecedents to propose and urge such an operation for a patient who had some lens opacity but who could still see to do fine sewing and read ordinary type with either eye

If the question of the significance of slight opacities of the lens were one rarely of practical importance, this subject might not be worth while discussing, but where it arises in more than three fourths of our patients who have reached the age of 75 years it is of great practical importance My own custom has been not to use the word "cataract" unless the opacity was causing serious impairment of vision, or likely to require operation In the other cases I have informed the patient of the existence of "lens opacity," and have explained its probable significance, only speaking of "cataract" in response to some direct inquiry as to whether it or anything like it was present I believe that such a course gives patients a far truer idea of their condition than one which calls all lens opacities "cataract" It seems likely that some such distinction of terms will in time arise It is probably useless to attempt by recommendation or resolution to introduce such a term, but if the need for it is clearly recognized and appreciated on the part of the profession, the differentiation of language will naturally follow

DISCUSSION

Dr F C Hotz, Chicago—I am sorry that I came in too late to hear the paper and only caught the closing remarks, from which I infer that Dr Jackson recommends the use of the term cataract only for rather advanced state of obscuration of the lens, so advanced that an operation will soon be necessary, and not to apply it to those slight opacities of the lens which may remain stationary for a great many years So far as the patients are concerned, I fully agree with the reader of the paper, and just as he has been in the habit of not calling it a cataract when it is only a slight peripheral opacity, so have I restrained myself from using that term in conversation with patients Certainly these opacities remain stationary for many years, for instance, I had this winter the opportunity to examine the eyes of a lady 69 years of age for a readjustment of her glasses, and she told me that thirty years ago she consulted Dr Agnew in New York, who told her that she had a cataract in one eye I was surprised at the information, because the vision in that eye was still 20/40 At the examination in the dark room I found some short, equatorial streaks in the lens, so that evidently, if the information was correct, and I have no reason to doubt the lady's word, these equatorial streaks existed thirty years prior to my examination As cataract is a condition which in the public mind is considered as a sign of advancing life, and as this lady after receiving the information from Dr Agnew might have gone to some of these renowned healers, or to that institution in New York State that cures cataract by absorption, or if she had meddled with Christian scientists, who claim to stay the threatening blindness, she certainly would have had apparently good reason for giving credit to such healers for the fact that her eyesight had been preserved for thirty years From such considerations I think it is a good suggestion on the part of Dr Jackson that we should not use the term cataract for all conditions of opaqueness or disturbance of the lens transparency

Dr G C Savage, Nashville—I should like to say a word relative to the causation of cataract I think that one cause is a diminution of the nutrition of the lens because of failure of ciliary power Whether we agree with Collins or not, that there are glands in the ciliary body which secrete fluid essential to the well being of the lens, we must agree that the lens gets its nourishment largely from the ciliary body in some way The more active the muscle of the ciliary body the better will be the nutrition of that body and the lens I believe it is just as possible to develop a ciliary muscle which is weak, or to prevent its growing weak, as it is to develop any other muscle of the body, and it seems to me that the patient should be given the advantage that can be derived from restoration of the ciliary's power I am approaching the age at which presbyopia usually comes, and more than a year ago I found it very difficult to extract foreign bodies from the cornea I was beginning to hold my paper and book farther from me than was comfortable I began then the exercise of my ciliary muscles and have now full restoration of power I mention this to show you that the ciliary muscle can be developed and old sight be delayed, perhaps indefinitely In this way may not the lens be made to retain its transparency as well as its elasticity for a long time? Thus we may be able to prevent the development of cataract This exercise is effected by means of weak, concave, spherical lenses (—S O D) in simple spectacle frames For ten minutes each night I sit down, with the light turned low, and with the view of keeping my young sight and maintaining lens transparency, I exercise my ciliary muscles I sit eight or ten feet from the light with my astigmatic glasses on, I raise and lower the exercise lenses at intervals of three seconds, for ten whole minutes I can read without the use of old sight glasses and I hope to be able to do so for years to come, and also hope to keep the nutrition of my lens so good as to prevent cataract

Dr Leartus Connor, Detroit—It occurs to me that if Dr Savage's rule is correct, there need never be any increase in the inorganic matter in our tissues if we only exercise enough It ought to be true of the biceps muscle as well as of the ciliary muscle All should retain the proportion of organic matter that exists in youth I should be very glad to think that my friend is right and that we have arrived at the basis of an elixir of life and need not die, for death comes from the increased proportion of inorganic matter in the several tissues of the body

I think, though, that the doctor is right in one point, that is that the improved nutrition of the lens, however effected, is a feature in preventing the increase of these opacities I have under my observation several persons in whom I recognized opacities in the lens, at times, varying from ten to eighteen years ago, who at that time had errors of refraction that were corrected, and the result of that correction has continued to the present time while the lens opacities scarcely changed I think it was from Dr Risley's paper, calling attention to the relation between the eye strain and the production of a cataract, that I got my suggestion on this point At any rate it seems rational that if you can prevent abnormally disturbed nutrition you can retain its normal transparency I think Dr Risley at one time collected a vast amount of statistics in Philadelphia showing the proportion of cataracts as seen many years before and the slight change that had occurred The result was that the greater attention to errors of refraction had diminished in Philadelphia the proportion of cataracts

The only objection I see to Dr Jackson's method, which I think is entirely sound, is that some other person may see the patient, tell him that he has a cataract, and the patient thinks the first examiner knew nothing about it Perhaps that might be overcome by telling some of the patient's friends

Dr Frank Allport, Chicago—I suppose that a recitation of extreme cases in this particular might be valuable We all see cases, from time to time, of opacities of one kind and another in the lens that do not increase from year to year, but Dr Hotz's case reminds me of an instance, which I re ported in one of the journals, though I do not remember now just where

A lady almost similarly situated came to me a year or two ago and while under ordinary circumstances I would not have paid so much attention to what she said, I was *forced to* believe what she said because she was the wife of a physician and a woman of unusual powers of observation She came for a correction of refractive error, and in the course of examination I noticed quite a considerable opacity at the periphery of the lens of both eyes I spoke to her about it and she said that twenty five or thirty years before she had been examined in New York I think by both Drs Agnew and Knapp, at least the former, and he told her to prepare herself for a cataract extraction in the course of a year or two Her vision never decreased and she could see just as well at the time I saw her as she did twenty five or thirty years before This shows that we might allow these patients to retain their mental equipoise for a long time rather than disturb them with the information that they have a cataract, which is synonymous in their minds with the rapid approach of blindness

I think we should tell them they have an opacity of the lens and not mention the word cataract, or else tell some of the friends of the family so as to protect ourselves We all know that the correct adjustment of glasses and the building up of the health will put off the full development of the cataract in many instances for a number of years and it seems too bad to have sensitive patients disturbed for many years unless it is absolutely necessary to tell them

Dr Jackson—I recall one case that is perhaps worth mentioning because it was seen by three or four prominent oculists It was an old lady, then about 60 years of age, who had lost vision rapidly until she could not see to read at all She had extensive lens opacity and it was expected that within a few months the cataract would be ready for extraction All her eye work ceased Pretty soon her vision began to improve somewhat, and it was found that it could be further improved by the aid of glasses, and in the course of a year or two she got back to reading Now, after over twenty years, she reads magazines, newspapers, etc , for several hours a day and does not suffer from her impairment of vision The condition is now one of almost entire opacity of the periphery of both lenses, with a small tunnel of clear lens substance right back of the pupil It is not a peculiar form of opacity, but I think it might happen in almost any case of cataract that the progress of the opacity might be checked, or so far as we know, cease spontaneously The point raised by Dr Connor that the patient may be alarmed by somebody else and think we had overlooked the condition might occur, is an important one I have discussed cataracts with my patients for the distinct purpose of preventing their being frightened by some one else Where I have watched the lens for some months or years, where I knew the cataract was not progressive and where it was likely the patient might pass into other hands, I have gone out of my way to give the patient a full account of the condition of his eyes, to guard against that risk I think this is just as important as it is to avoid the term cataract in many instances

---

A FORM OF CORNEAL TURBIDITY EASILY OVERLOOKED

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7 10, 1898

BY H GRADLE, M D ,
CHICAGO

The form of corneal cloudiness to which I wish to call your attention escapes detection when the eye is examined by either direct or ophthalmoscopic inspection Apparently the cornea has its normal lustre and transparency The turbidity is only detected on using a highly magnifying lens with lateral illumination It is of course known that the normal cornea is a turbid medium This can be shown strikingly when we use an electric light for focal illumination, and throw a sharp image of the incandescent filament upon the corneal surface It seems to be less well known that the turbidity revealed by the focal illumination can be resolved by a strong lens into a granular appearance There are differences in this respect between apparently normal eyes The more turbid the cornea, the better defined the grain I may add that by this method of examination other anomalies of corneal transparency may be found, which escape detection otherwise A strong lens will reveal quite an amount of diffuse cloudiness around opacities, which, even with ordinary lateral illumination, seem well circumscribed I have observed too, after some cataract extractions, that imperfect vision may be due to a corneal haze which I was unable to demonstrate by other modes of examination

The form of corneal turbidity which is the object of this paper, appears simply as an exaggeration of the normal cloudiness When both eyes are alike, it is difficult to say whether we observe the normal haze or a moderate exaggeration, unless the turbidity, and especially its granular nature, is very pronounced If, however, the trouble is one sided, the comparison between the two eyes proves decisive

I have observed this corneal turbidity in patients complaining of asthenopic symptoms, with, however, more burning, smarting, or a feeling of "foreign body" than is usually mentioned in connection with refractive errors The eyes become blood-shot on continued exertion While the turbidity can not be seen with the ophthalmoscope, it still interferes with vision enough to lower it below the normal, even after the most painstaking correction of existing errors It has seemed to be somewhat characteristic that these patients were uncertain in their answers regarding the influence of glasses, to an extent rather striking in view of the nearly perfect vision

I will first quote the one-sided instances, as they are the most conclusive Both the patients had bilateral errors, but complained essentially of the one eye It was noticeable that the eye was irritated, as it presented a slight, but unmistakable inflammatory ptosis There was no ciliary injection, but the deep scleral veins next to the upper and lower transition folds were prominently distended On focal illumination and inspection through a short-focused lens the cornea of the irritated eye presented distinctly more interstitial haze and fine "dottings" than the other eye, otherwise the eye showed no anomaly that could account for the lowered vision

Case 1 —Mrs L , 53 years of age Complained since many weeks that the left eye feels weak and gets tired on exertion, and ultimately begins to burn and becomes slightly blood shot She has changed her formerly satisfactory glasses to 3, 5 D, but without benefit The right eye appears externally normal The lid aperture of the left eye is slightly smaller, and the left lids are a trifle more vascular than the right On exposure the scleral veins next to the transition folds are visible in the left eye The conjunctiva is normal, but everting it causes a trifling superficial injection on the eye ball Tension, pupils and fundus normal in both eyes Lateral illumination and the use of the lens show an unmistakable difference in the turbidity of the two corneæ

R E V $^{20}/_{100}$ Sph+1 5=20/[illegible]
R E V $^{20}/_{100}$ Sph+1 & Cyl+1 axis 180=$^{20}/_{10}$

Being somewhat uncertain how to interpret the condition which I did not think was fully accounted for by the astigmatism, *I advised rest of* the eyes and the inspersion of calomel in the left eye One week later the same objective appearances, but with comparative comfort except on use of the eyes She was advised to use for work,

R E +3, 5
L E +3, & *Cyl* +1 axis 180

One week later she expressed herself satisfied, but the objective appearances were unchanged One month later she admitted that she had even less discomfort in the left eye than at first when she began using her glasses The objective difference between the two eyes still existed, but was less pronounced than originally The calomel had been continued during this time

Case 2 —Miss S , 35 years of age Has noticed since years a small, faint spot of circumscribed redness on the external part of the sclera of left eye Four years ago there appeared a "blister" on this spot which soon healed On account of headaches she received glasses (R Cyl —1, axis 180 , L Cyl —1, 25 25 axis 180 & Sph —0 5), which gave her relief The left eye has, however, remained smaller than the right, and is sometimes bloodshot Lately she has had more or less burning pain in the left eye only The right eye is externally normal, with *the exception of slight distention of scleral veins next to the* transition folds The left lid aperture is smaller, the lids a trifle more vascular, the scleral veins at the periphery a trifle fuller than in the right eye On the sclera of the left eye external to the cornea, there is a small, red spot made up of separate dilated vessels, but without any inflammatory appearance (hence, no episcleritis) The conjunctiva is slightly vascular in the superior transition *folds* in both eyes Lateral illumination with magnification shows the left cornea decidedly more turbid and "dotted" than the right The only ophthalmoscopic anomaly is a large conus downward in both eyes

R E 20/10 Cyl —1, 25 axis 180=20/20—
L E 20/10 Cyl —1, 25 axis 165=20/10—

(With some uncertainty)

Her glasses were changed, and one week later she expressed herself as nearly satisfied She was ordered to insperse calomel Eight months later she returned She had lost all complaints after using calomel for a few weeks except the objective appearance, but since some weeks she has again more or less *steady discomfort in the left eye,* in the form of burning and scratching, increasing on exertion The objective appearances are the same as the previous year except that the difference between the two eyes is not so pronounced As far as one can judge in such subtle matters, there is less haze of the left cornea than previously, but a little more scleral vascularity on the right side There is, however, still slight but unmistakable *narrowing of the left lid aperture* She has now been under observation three months, and has nearly lost the objective appearances as well as the subjective discomfort, yet the treatment was hardly more than expectant She has used calomel in both eyes, paid some attention to general hygienic measures, but has not abstained from moderate eye work Although the left cornea seems to have cleared slightly, the vision has not improved, but her answers on refractive examination are more positive than formerly

In the following cases the disease was not one-sided, but more pronounced in one eye than in the other The cases are, therefore, not as clear as the two previous instances

Case 3 —Mrs K , 27 years of age The eyes get tired on use, and exertion gives her dull frontal headache Since three months she has a feeling of a foreign body in the left eye, which is sometimes bloodshot The eyes and conjunctival surfaces are not reddened, but in the periphery the scleral veins are fuller than normal The left eye appears a trifle smaller than the right There is increased corneal haze apparently alike in both eyes—of course only visible by focal illumination Fundus normal

R E V=20/60 Cyl —1 axis 90 & Sph —75=20/25
L E V=20/60 Cyl —1 axis 95 & Sph —1 5=20/30

She was ordered to wear Cyl —1 and Sph —0, 75, which proved most comfortable on trial *Twenty two months later* she returned, stating that the glasses had relieved the pain and headache, but for a while she still felt slight irritation in the left eye, and is probably not absolutely free from it yet The objective condition is the same as previously The left lid aperture a trifle *smaller than the right*

Case 4 —Mrs M , 29 years of age Is in poor health since her last confinement, has pelvic disease Since half a year she gets tired from eye work, which ultimately gives her a headache The eyes are apt to become bloodshot, and the lids *often droop so as to* give her a sleepy appearance The right eye is a trifle smaller than the left The *ophthalmoscope* shows the edge of the right disc slightly blurred The corneæ show both more than the normal *turbidity*

R E V 20/40 Cyl +0 5 axis 180 20/35
L E V 20/10 *Cyl +0* 5 axis *180* 20/30

She was ordered Cyl +0 5 and the use of calomel as well as *general hygienic* measures, as I did not think that the local condition explained fully her complaints However, *two weeks* later she admitted that she was much better, though still not able to use her eyes *indefinitely without some suffering*

Case 5 —Miss S , 41 years of age Had suffered much with headaches in the form of migrain, which two years ago were said to have been relieved by the use of a Cyl +0, 5 axis 90 Lately she has again had more headache, probably from close application to study and want of exercise On steady exertion she gets burning in the eyes I found the refraction fully corrected by her glasses, though her sight did not reach quite 20/20, especially in the left eye Her accommodation was normal I ordered only hygienic measures, which proved sufficient to give her relative comfort

Six months later she returned, claiming to be fairly well satisfied, except that she still has burning of the eyes, lately somewhat more annoying There is no injection whatsoever, but *unmistakable increased turbidity* of the corneæ, and in the left eye more than in the right At the previous time she had not been examined in this respect As her accommodation seemed slightly insufficient, she was advised to use Sph +0 75 for a trial for work, but she has not reported the result

Case 6 —Mrs H , 57 years of age Slightly tired on use of the eyes Occasional migrain Comes mainly on account of twitching of the left upper lid The only anomaly found was a difference in the transparency of the two corneæ, the left being a trifle more hazy on focal illumination, and presenting a decidedly more marked—relatively coarse—grain

R E V 20/40 Cyl —0 5 axis 165=20/30
L E V 20/50 Cyl +1 axis 135=20/30

Although she could decipher a little more positively with the left eye after *correction* than with the right, she was still definite in her statement that the letters seemed more blurred to the left eye than to the right The above glasses given to her proved, however, satisfactory

Case 7 —Mr T , 20 years of age Sight is blurred at times *to a* variable extent Headaches from long use, and the eyes get red and watery, the watering being more annoying on the right side He had *lately obtained glasses* (R E Cyl —0,75 axis 180 , L E Cyl —0,25 axis 180 & Sph —0,5), but was quite doubtful as to their value I found his optic condition,

R E V 20/10 Sph —0,5 & Cyl —0,5 axis 90 20/30,
L E V 20/40 Sph —0,5 & Cyl —0 5 axis 90 20/30,

with considerable hesitation concerning these glasses The corneæ were both decidedly turbid and almost stippled, so that there could *be no doubt about its being* a *morbid* condition, yet neither direct inspection nor ophthalmoscope showed this anomaly There was slight congestion of the palpebral conjunctiva, but no actual catarrhal condition The lachrymal puncta seemed normal on the left side, while on the right the lower one could not be found, and the upper one appeared unusually small As I could not account for the watering, except on the supposition of a lachrymal stricture, I divided the right upper canaliculus down into the sac, finding indeed much obstruction in the path In view of the corneal condition, I suggested calomel to be dusted in Contrary to my expectation, the blurring and watering improved decidedly in the course of a fortnight On using the probe a few consecutive times, the patency of the right passage was easily maintained The left lachrymal channel was never examined At the end of the third week he was contented to stop further treatment as he was practically free from complaint, and his vision had risen to 20/30 As far as one can judge, both corneæ appeared less turbid

Four months later I found him free from discomfort, no more watering, vision satisfactory, though only 20/30, and the cornea apparently not as turbid as originally He accepted the same cylinders as before, but was doubtful about the concave spherical glass He felt, however, no need for glasses

All these patients had refractive anomalies, but these errors did not account fully for the complaints in the majority of instances, especially the one-sided ones There was more burning and external irritation than is found in typic cases of refractive errors While glasses were of benefit in all but the last instance, *they did not* give immediate and prompt relief to all symptoms In the last instance, indeed, the complaint ceased even without optic correction

Yet the refractive anomaly seems to me of some etiologic importance since the more ametropic eye showed the most irritation and the greater corneal turbidity in all anisometropic instances

It was noticeable that these patients showed more than the ordinary hesitation in choosing glasses In none could I obtain absolutely perfect vision A condition of irritation was manifest in the one sided instances, and in some of the unequal bilateral ones, by the slight but unmistakable ptosis Indeed, it was this symptom which induced me to use lateral illumination, in the expectation that I might find a minute circumscribed corneal infiltrate as the possible lesion Instead of this, however, there was the increased corneal turbidity entirely diffuse and not circumscribed I do not consider this a keratitis, as there was neither dimness of lustre nor opacity recognizable by the ophthalmoscope Yet there must have been some irritative lesion, as suggested by the slight ptosis, as well as the fullness of the scleral veins next to the transition fold The conjunctival congestion noticed in some was not always present, and hence was either secondary or irrelevant As to the nature and exact site of the irritative process, I can not express an opinion The corneal turbidity seems to me a secondary consequence, probably due to lymphstasis It seems to account however, for the imperfection of vision

The irritative condition here described, is, I believe, a not infrequent bilateral occurrence, and, as such, a factor in many instances of rebellious asthenopia But when bilateral the diaganosis is difficult For the very symptoms which suggest it, the slight inflammatory ptosis, the vascularity of the sclera next to the fornix, are so little pronounced that they are scarcely observed unless unilateral and thus accentuated by comparison The corneal turbidity itself is, as I emphasized, but an exaggeration of the normal condition As the normal turbidity varies somewhat, the diagnostic judgment is easily at fault, unless the haze is relatively coarse or a difference between the two corneæ facilitates the comparison The first bilateral case, however, that I observed not quite two years ago, showed such a marked turbidity and coarse "grain' that it could be easily and positively pronounced morbid, indeed, I hesitated whether or not to call it keratitis Unfortunately I saw that patient only once, probably because the correction of her astigmatism proved relatively satisfactory I have records of five other patients whom I would place in the same class They all had more or less burning or smarting sensations not fully accounted for by their ametropia, as this was either minimal, or as its correction gave only partial relief On using the eyes they became bloodshot In all cases the vision was not quite equal to 20/20, and glasses, if accepted at all, were passed upon with much hesitation In all these instances the corneæ seemed to me less than normally transparent In some my diagnosis seemed definitely established, in others I remained in doubt on account of the feebly pronounced objective appearances I can recall many instances besides that presumably belong to this group from my former experience before I used lateral illumination in such patients systematically, but of course lack the essential objective criterion in my records

DISCUSSION

Dr L J **Lautenbach**, Philadelphia—I think any one who uses the ophthalmometer extensively will have noticed a large class of cases of opacity of the cornea not recognizable by the usual methods of examination No ophthalmoscopic examination is equal to that which we get by taking the incandescent filament as our source of light, using its reflected lines to indicate the exact contour of the inside of the eyes as well as of the corneal layers It is one of the best ways of carefully studying the corneal nutrition The ophthalmoscope thus gives us knowledge not obtained in any other way I simply mention this to call attention to the advantage of having the best instruments for bringing out the various fine anatomic and pathologic points

The causation of these cases seems to me to reside in a disturbance mainly dependent upon blood conditions These cases usually give a rheumatic or syphilitic history, though it is not always present I expect in a very short time to bring forth a paper covering this very ground It covers the case of a patient who was operated upon for cataract and where this peculiar opacity of the cornea has been greatly controlled by the use of glasses In another similar case I am not using glasses, but with the knowledge of the man, am studying the changes that are taking place in his cornea

Dr **Edward Jackson**, Denver—I have seen a few cases such as Dr Gradle refers to, and I agree with him in thinking that eye strain is a very important factor in the causation The condition has yielded to the persistent use of one of the slow mydriatics, used sometimes for three or four weeks

Dr **Harold Gifford**, Omaha—When Dr Gradle announced the subject of his paper to me I thought it time to say something of a form of opacity which I have been demonstrating to my friends for some years I have called them normal opacities of the cornea I have never yet seen a cornea which with proper illumination and examination you could not dissolve the haziness into little spots and clouds distinct from one another This is not easy to see and recently when I tried to demonstrate it to some gentlemen in New York, I failed entirely for want of a proper lens The haze which you see with the ordinary pocket lens resolves itself when you get a magnifier of five or ten diameters into these little clouds I think the explanation of that is that they represent the so-called corneal corpuscles and they are more prominent at times because of their filling up with leucocytes and that may account for the changes taking place under eye strain I am sure that it is a perfectly normal condition and that any of you who take the proper means can demonstrate it to your satisfaction If there is the slightest sort of irritation, be it an ulcer or foreign body, you will at once find these opacities much larger and tending decidedly to run into each other They are more easily seen with a dilated pupil

Dr J F **Fulton**, St Paul—I am very glad that Dr Gradle has introduced this important subject, because it covers a class of cases that has embarrassed us very much There is no doubt they are due to strain of some kind and in many cases I think is a stage of active keratitis This condition is not only due to refractive trouble, but frequently to muscular trouble, and anything that relieves the strain will improve the condition It becomes therefore important not only to correct refractive errors, but to correct the muscular condition

Dr **Gradle**—I mentioned the incandescent filament as a method of examination to show the normal turbidity, but it has no clinical advantage I can confirm what Dr Gifford said about the normal cornea The haze can be resolved into fine dots or clouds and sometimes into a few comparatively coarse dots It is difficult to say on examination of an eye whether the turbidity you find is more than normal or not I can not do it except in one sided instances or in those cases of bilateral trouble where the turbidity is decidly increased

I consider this condition very common, for I have on record at least six cases since I began to observe the trouble two years ago, of the same condition existing in both eyes uniformly, but the difficulty of diagnosis here is great The cases are asthenopes that complain of external irritation of the eyes, sandy feeling, burning, etc But the pronounced symptoms of the one sided cases fail us in some of these bilateral cases The first case I saw was so pronounced that I wondered whether or not it was keratitis The other cases were not so pronounced, but in all there was sufficient turbidity to enable me to say that there was deviation from the normal

BACTERIA ONE OF THE CHIEF ETIOLOGIC FACTORS IN DISEASES OF THE EYE

Presented to the Section on Ophthalmology, at the Forty ninth Annual *Meeting of the American Medical Association*, held at Denver Colo June 7-10 1898

BY ELLET ORRIN SISSON, M D

Professor of Anatomy and Director of the Microscopic and Bacteriologic Laboratories, College of Physicians and Surgeons Keokuk Iowa

KEOKUK IOWA

While the relation of bacteria to general diseases has been proven beyond a doubt, and with the result that the practice of medicine and surgery has been practically revolutionized, and placed on a more thorough scientific basis than at any time in its history, the special field of ophthalmology has also received attention, and although we have but entered upon this line of research, we are able to report several important discoveries which are of inestimable value to the ophthalmologist, and which will undoubtedly be followed by others, serving to explain many hitherto misunderstood phenomena

It is perfectly reasonable to suppose that bacteria should be one of the chief etiologic factors in the production of diseased conditions in the eye, when we take into consideration the exposed position of the organ We have the moist surface of the conjunctiva presenting itself and furnishing an excellent lodging-place for all sorts of deleterious substances present in the air It is rubbed by soiled fingers, washed with impure water from rivers, creeks and ponds, wiped with soiled towels, handkerchiefs, and whatever else comes to hand Moreover, the slight alkalinity and small amount of proteid material contained in the normal secretions, as well as the fact that there are folds and crypts in the conjunctival membrane, favor the development of whatever germs accidentally enter But aside from all these means of infection, an even more dangerous source of contamination is from the nose by way of the nasal duct and lachrymal sac, the continuity of the mucous membrane between these structures furnishing an excellent means of conveyance for saprophytic and parasitic (pathogenic) organisms from the nose to the eye and vice versa Again, infection of the conjunctiva may occur from disease of neighboring bones and an inflammation of the sinuses, especially the maxillary sinus, or it may appear by the conveyance of micro organisms to the conjunctiva through the blood- and lymph-vessels in cases of diseases of remote organs

The various researches of Sattler, Michel, Fick, Weeks, Shongolowicz and many others, have clearly established the constant presence of numerous harmful as well as harmless bacteria upon the eye, and by this demonstration have shown a factor in prognosis which had not previously been considered

Among the diseases in which the causative rôle is played by bacteria, we note first acute catarrhal conjunctivitis, that this condition is of microbic origin there can be no doubt Gifford,[1] in an examination of forty cases of acute catarrhal conjunctivitis, ascertained the cause to be the pneumococcus of Fraenkel, which, according to the researches of Gasperini, as reported at the Eleventh International Congress in Rome, is shown to be one of the most frequent microbes that inhabit the conjunctival sac Gifford proved that the pneumococcus really caused the disease, by successful experiments in inoculating with pure cultures According to Weeks, acute catarrhal conjunctivitis is caused almost exclusively by a small bacillus which he was the first to study thoroughly, and his observations have been confirmed to a large extent by Moran and Beach In acute blenorrhea of the conjunctiva or purulent ophthalmia, the etiologic moment is the introduction into the conjunctival sac of some of the specific discharge from the urethra or vagina containing the gonococcus of Neisser Kroner[2] examined ninety-two cases of ophthalmia neonatorum and found the gonococcus with "perfect ease" in sixty-three of them In other cases it was difficult to find, but was successfully demonstrated Dr Th Gelpke[3] recently, in a very interesting article, reports the results of a bacteriologic investigation carried on in conjunction with Professor Migula in an epidemic of acute purulent ophthalmia After very careful observations they determined the cause to be the bacillus septatus Koch and Gaffke found in a highly contagious conjunctivitis small rods resembling those of mouse septicemia, and Kartulas succeeded in growing the same on agar as fine gray points, becoming confluent, making a stripe having a fatty appearance, which he considered as identical with the Leber-Kuschbert xerosis bacillus, but this Gelpke doubts after examinations of Leber's preparations Schmidt found a form morphologically resembling the albus, and Parinaud one resembling the gonococcus, which Morax identifies as the streptococcus

Another disease which, as we all know, is of bacterial origin, but which fortunately is rare, is diphtheritic conjunctivitis Here, in the majority of cases, we have the disease extending by the avenue previously neglected, namely, from the nose by way of the nasal duct and lachrymal sac Fuchs[4] says von Graefe observed many cases of diphtheritic conjunctivitis during epidemics of diphtheria in Germany, that "in lands where diphtheria prevails the disease appears, either sporadically or as an epidemic," that "at the time of an epidemic of diphtheria, other inflammations of the conjunctiva show a tendency to assume all at once a diphtheritic character" Fraenkel and Uhthoff have found that diphtheria bacilli are not uncommon in the conjunctival sac Escherich reports two cases in which diphtheria bacilli were found in the exudate In the same category as diphtheritic conjunctivitis comes tuberculosis of the conjunctiva caused by the bacillus tuberculosis of Koch This condition is usually secondary to general tuberculosis, but Cheney of Boston reported a case before the American Ophthalmological Society, 1896, where the primary lesion appeared on the conjunctival surface of the left upper lid, and presented a typic appearance Tubercle bacilli were found on microscopic examination The glands in front of the ear were affected when first seen Frequent examination of the chest failed to elicit any trouble in the lungs Patient disappeared from the clinic, May 26, and July 1, died of general tuberculosis The main trouble just preceding her death seemed to be in the throat E Franke reports a case where, in a seven-year old boy of healthy parents there appeared numerous blisters on the ocular conjunctiva, and little follicles in the retrotarsal fold of the lower lid, together with swelling of the pre-auricular gland of the right side In a piece taken for examination there were giant cells and tubercle A small portion of the excised conjunctiva was placed for experiment in the anterior chamber of a rabbit's eye, a tubercle of the iris formed in which bacilli were found In the case of the boy, the entire diseased spot of the conjunctiva was removed, together with the pre auricular gland For a year afterward the boy remained without eye disease

Bacteriologic research in connection with xerosis or xerophthalmos has resulted in the discovery of a bacillus which is believed by many investigators to be the cause of the disease In the experiments conducted by Kuschbert and Neisser with this bacillus a moderate inflammatory reaction was obtained, while Leber describes a catarrhal condition of the conjunctiva which might be somewhat due to staphylococci present, and as previously mentioned, it has been confounded with the bacillus kartulis In short, the descriptions of the xerosis bacillus are, in its morphologic and biologic relations, somewhat conflicting, so that only carefully conducted observations and experiments will succeed in establishing it as the micro organism of xerosis

The first bacteriologic "arbeit" upon trachoma seems to have been done by Sattler,[5] who found small cocci of biscuit shape, joined in pairs but separated from each other by an intervening space, and in size and appearance much resembling the micrococcus gonorrheæ This organism, described by Sattler, though it resembles the gonococcus, is certainly a different organism Baumgarten and also Kartulis have taken exception to its specific action, by showing that it was absent in many cases of ordinary trachoma and in the cases of the virulent ophthalmia of Egypt While in Egypt in 1882 and 1883, Koch paid some attention to the ophthalmia prevalent there, and he reports that the cultivation experiments from the conjunctiva of these cases discovered the presence of the gonococcus and a tiny bacillus Michel[8] found in numerous cases of Egyptian catarrh a diplococcus much resembling the gonococcus, but smaller While both of these observers were in accord as to the shape and size of the organisms found by them, the latter alone was successful in his inoculations Schmidt[9] differed again, and continually found in the secretions small, perfectly round, isolated cocci without a dividing septum, surrounded by a clear, gelatinous area, and resembling the staphylococcus pyogenes aureus They occurred free and also in the protoplasm of the epithelial cells In this connection let us point out that the morphology of the staphylococcus pyogenes aureus is now well known to be exactly that which Schmidt rejects Schmidt found that the organisms which he observed readily induced trachoma in birds, which were very susceptible, but that mammals contracted the disease only after numerous repeated inoculations His studies were thorough, comprising sixty-three cases, in forty-nine of which this coccus was found

Kucharski[10] investigated twenty six cases of trachoma and found numerous bacteria, among which were staphylococcus pyogenes aureus, bacillus subtilis, bacillus mesentericus vulgatus, when these accidental organisms were excluded, his cultures all showed one characteristic organism This organism was a diplococcus of the size and shape of the gonococcus, possessed of a "springing movement" Sometimes it was seen to occur singly, sometimes in groups, sometimes short chains were observed, sometimes a figure 8 The description of his coccus is thorough and excellent Unfortunately, while it did not seem specific, he concluded to add it to the literature of trachoma Goldschmidt's[11] coccus corresponds very closely to that of Michel

Very remarkable results were obtained by Washejewski,[12] who studied thirty cases of trachoma in its various stages He found single cocci and groups of cocci enclosed in the lymphoid cells, the red blood corpuscles and the epithelial cells He was unable to find any other organisms The cocci thus enclosed in the cells resembled the gonococcus

Staderini[13] found a coccus much like the cocci already described Its morphology was very similar to that of the gonococcus Baumgarten investigated this organism and could not see that it differed from the staphylococcus pyogenes aureus

Wittram[14] studied thirty-nine cases of trachoma and discovered cocci similar to those of previous authors, but as far as he could determine, inoculation experiments were all negative in their results

Shongolowicz[15] introduced an interesting innovation in the etiology of trachoma by describing a specific bacillus which he found in seven out of numerous cases which he studied Inoculations of pure cultures of this bacillus under the skin of two white mice, one guinea pig and one rabbit gave no results Sixteen inoculations of pure cultures of the bacillus upon the conjunctiva of five rabbits, two dogs, four pigeons, one guinea pig, two white mice and two cats, were all productive, not of trachoma, but of a somewhat similar disease

Alt,[16] in a paper read at the last meeting of the Western Ophthalmological and Oto-Laryngological Association, entitled "Recent Researches in the Histo-Pathology of Trachoma," reports as the result of his investigations, which have been very thorough, the finding of a parasite which he deems the cause of the disease He found them in follicular conjunctivitis as well as in trachoma From the similarity of the climatologic conditions under which malaria and trachoma seem best to thrive, Elze,[17] like many another before him, drew the conclusions, that the same or similar cause must bring about both these diseases He observed, in one case, in the secretion, as well as in the granules, certain formations, which he thinks are monads and which he especially likens to the trichomonas batrachorum, and proposes to call plasmodia

Thus the bacteriology of trachoma is of special interest, and, while the majority are inclined to the opinion that at the present moment we have no reason for regarding any bacteria as specific for trachoma, still no one will deny that the bacteriologic researches in connection with the disease have been productive of much good, as everything points to its being a germ disease, and as we have seen, there seems to be a pretty well established connection between trachoma and gonorrhea, and it is not improbable that the rôle played by the gonococcus is of more importance in the etiology of trachoma than is generally supposed

Passing to diseases of the cornea, careful observation and study go to prove that many corneal troubles are dependent directly or indirectly upon invading bacteria Leber has shown how serious may be the results of a growth of comparatively harmless organisms if once they secure a footing in the proper soil, and reason exists why we should believe that keratitis may result from ordinarily harmless bacteria should they gain entrance to the corneal layers Babes obtained from the broken down corneal tissues and from various organs of a child who died of septicemia following keratomalacia, a bacillus which he terms the bacillus septicus keratomalaciæ Cultures of this bacillus inoculated into the cornea caused purulent keratitis

The capsule bacillus of Loeb was also obtained from a case of keratomalacia infantum by inoculating media with a little of the softened exudate of the cornea It resembled the bacillus capsulatus of Pffeifer, but is said to be somewhat larger and thicker than the latter

Experiments with the bacillus of Fick,[18] which has been found in the conjunctival sac, showed that when inoculated into the corneal tissue the organism produced a distinct keratitis, and sometimes caused a perforating ulcer, which required about four weeks to penetrate the corneal tissues The work in this field has but just commenced, and bacteriologic research will undoubtedly reveal much which will be of value in connection with corneal diseases

There is one more disease which I must consider before closing this paper, first because of its importance, and second because it is recognized by all authorities to be directly produced by bacteria I refer to sympathetic ophthalmitis This affection, as we know, owes its name to the theory, held until a few years ago, that it was due to reflex action of the ciliary nerves Investigations made in recent years[19] have placed it beyond doubt, that sympathetic ophthalmitis is an inflammation propagated to the sympathizing eye by direct continuity through the optic nerves and chiasm from the exciting eye, as erysipelas extends over the skin, and that the staphylococcus pyogenes albus or aureus is the active element in the process

Time will not permit a further discussion of this interesting subject, and as I have repeatedly said throughout this paper, the work has but just commenced, and in view of the fact that besides the bacteria occurring in connection with the diseases mentioned, and which we have no right to deny is the direct cause of them, we have to deal with such bacteria as the bacillus coli communis, bacillus influenzæ, bacillus lepræ, bacillus of measles, bacillus pyocyaneus, bacillus syphilis, staphylococcus, pyogenes citreus and streptococcus pyogenes, some of which have been demonstrated as occurring in the conjunctival sac and we have no reason to believe that the others do not, I think we are perfectly justified in believing that bacteria are one of the chief etiologic factors in diseases of the eye

CONCLUSIONS FROM CLINICAL AND BACTERIOLOGIC EXPERIMENTS WITH HOLOCAIN

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo June 7-10 1898

BY ROBERT L RANDOLPH, M D

BALTIMORE MD

I have been using holocain for some months and have recorded here fifty cases where it was recently employed in the eye clinic of the Johns Hopkins Hospital Seventeen of these cases were foreign bodies in the cornea, and the average time employed to produce anesthesia was a little less than two minutes In three cases iridectomy was performed and in four cases cataract extraction Here I made the same number of instillations as I do when employing cocain, that is three in fifteen minutes, and all that can be said is that I noticed no difference in the anesthesia from that produced by cocain, and the same may be said of eight tenotomies The other cases were where the holocain was used after the application of silver nitrate, after the passing of probes, in operations for tarsal cysts and pterygia With the exception of the tarsal cysts the anesthesia was produced in a little more than two minutes Most of those who have reported on the subject of holocain have alluded to its germicidal properties I have looked through the literature, and with the exception of some very meager experiments made by Heinz, showing that the yeast bacteria are retarded in their growth by contact with holocain, have found no record of experiments proving that a solution of holocain is a germicidal one The following experiments were made to throw some light upon this aspect of the question

1 *To determine the effect of a 1 per cent solution of holocain upon the micrococcus epidermidis albus* (Welch) For this purpose thirty wooden toothpicks were sterilized by boiling for ten minutes They were then immersed for five minutes in a suspension of the organisms in sterilized water, afterward taken out and dropped into a 1 per cent solution of holocain Here they were allowed to remain fifteen minutes They were then taken out with long sterilized forceps and plunged each into a tube containing nutrient agar After being in the thermostat twenty-four hours they were inspected, and in every tube there was a luxuriant growth Control tubes showed that the pieces of wood were sterile before immersion in the suspension of organisms The growth in half of the tubes was examined and the micrococcus epidermidis albus was found in every instance Fifteen

experiments made with the staphylococcus pyogenes aureus resulted in the same manner In another series glass rods were employed instead of pieces of wood They were sterilized in the flame They were then dropped into a suspension of the aureus in sterilized water and allowed to remain there five minutes When taken out, instead of putting them directly into the holocain solution as was done in the first and second series, they were put into a sterile tube and allowed to dry thoroughly and then immersed fifteen minutes in a 1 per cent solution of holocain, after which each rod was plunged into a tube of nutrient agar The result was the same as in the first and second series

2 *To determine whether a 1 per cent solution of holocain has an inhibitory effect upon these same organisms* Five grains of holocain were dissolved by boiling in two drams of water, and to this were added six drams of fluid agar The resulting mixture was practically a 1 per cent solution of holocain Twenty tubes of "slant agar" were prepared in this way and ten "smear cultures" made of the staphylococcus pyogenes aureus and ten of the micrococcus epidermidis albus These tubes were inspected every day for three days but there was never any evidence of a growth This experiment was repeated a number of times by others in the laboratory as a control measure, and in every instance with the same result Neither the staphylococcus pyogenes aureus nor the micrococcus epidermidis albus would grow in a medium containing holocain in the proportion mentioned It may be said that a solution of holocain half the strength employed in these experiments does not inhibit these organizations The positive results of the experiments to determine whether holocain had an inhibitory effect upon the organisms would seem to indicate that some of the organs on the glass rods and pieces of wood in the first, second and third series were killed To determine this question the following experiments were made

A thick suspension of the staphylococcus pyogenes albus was made in physiologic salt solution Five loops of this suspension were transferred to a tube containing two drams of a 1 per cent solution of holocain, and five loops were transferred to a tube containing the same quantity of salt solution, the latter as a control measure After allowing the organisms which had been transferred to the holocain to remain there five minutes, two loops of the latter solution were carried into fluid agar and plate cultures made This was repeated after ten, fifteen, twenty and thirty-five minutes, and finally, after twenty-four hours In the first plate (after five minutes) there were fifteen colonies, in the second plate (after ten minutes) there were about the same number, in the third plate (after fifteen minutes) there were five colonies, after twenty minutes three colonies, after thirty-five minutes two colonies, and finally, after twenty-four hours, the plate was sterile This series was repeated and with practically the same result There was a gradual diminution in the number of the colonies, the longer the organisms were allowed to remain in the holocain, and after twenty four hours it was seen that the holocain no longer contained living organisms Plate cultures made after twenty-four hours from the salt solution showed numerous colonies

Conclusions —Holocain, in so far as its anesthetic properties are concerned seemed in these fifty cases to have been sufficiently effective In those cases where a test was made of the rapdity of its action, as for instance in foreign bodies in the cornea, in pterygia, and after the application of irritating substances the quickness with which anesthesia was produced was striking Whether the anesthesia produced after two minutes is sufficiently profound to guarantee a painless iridectomy or a satisfactory cataract extraction I did not determine, but in those cases where operations of this character were performed, and where the holocain was instilled just as we do cocoain, no difference was observed in the anesthesia from that produced by cocain The drying of the cornea and dessication of its epithelium, the dilatation of the pupil, the absence of which phenomena has been noted by others has been confirmed by my own observations The absence of these two properties should recommend it for office use for the removal of foreign bodies, as it is well known that after the employment of cocain in such cases blurred vision and slight photophobia are often present for hours

A 1 per cent solution of holocain has not only an inhibitory effect upon the pus organisms, but these organisms are killed when exposed to a solution of this strength for a certain length of time No attempt was made to determine the point of time at which these organisms lose their vitality on exposure to holocain, but it may be safely said that this point is somewhere within twenty-four hours Furthermore, exposure to a 1 per cent solution of holocain for periods of five, ten, fifteen, twenty-five and thirty-five minutes showed in every instance a gradually diminishing number of colonies in the plates, so that it is plain in spite of the luxuriant growth around the glass rods and pieces of wood many of the organisms were killed It may be said in conclusion then that a solution of holocain of the strength employed in ophthalmic practice possesses distinct germicidal properties, a fact which it is evident enhances the value of this product

DISCUSSION

Dr H V WÜRDEMANN, Milwaukee—I have been unable to make any experiments regarding the antiseptic properties of holocain solutions, but as far as my experience goes I should say its solutions are stable and antiseptic A solution which I had and kept for the purpose of seeing whether it remained aseptic, though opened from time to time during eight months, shows that the solution remains clear and that it is antiseptic I am pleased at the exhaustive character of Dr Randolph's paper, for it seems to prove the claims that Tauber, Heintz and I have made

As regards its clinical aspects I have had much experience having used it as a local anesthetic in almost all of my bulb operations during the last year I have done several hundred operations with holocain, from corneal and conjunctival to cataract operations I have found it similar in effect to cocain but it has several advantages It more thoroughly anesthetizes the deeper structures, and its effect is more lasting It does not affect the accommodation, the pupil or the tension It is quicker in action, and does not affect the epithelium of the cornea That is a most important point, one can anesthetize an eye for a half hour or an hour, leaving it exposed to the air, but keeping it moist from time to time, and will not find any erosion of the epithelium We use less of the drug than of cocain, the percentage of the solution being only 1 per cent., and it is hence proportionately cheaper

As a disadvantage, it is said that it is more poisonous than cocain I have not had any ill effects from its use on the eye, nose or fauces, but I have not used it hypodermically The bleeding is more free than under cocain, and it is not so good for muscle operations It is slightly more irritating, and I have had patients complain after the removal of a foreign body that the sensation remained for some time, which is not the case after the use of cocain Another disadvantage to those of us who boil our instruments in soda solution is, that it is necessary to wash the instruments in sterilized water, because the soda is precipitated and the solution becomes turbid

I should say, from my experience with it in about fifteen cataracts, seven iridectomies, four operations for glaucoma and a number of minor operations, that this drug is a most satisfactory local anesthetic, and I recommend it especially for office work

Dr E C Ellett, Memphis—I have had a little experience with holocain during the past winter, limited to its use in removing foreign bodies from the cornea and conjunctiva, and with cataract extractions associated with iridectomy I have done seven or eight cataract extractions in that time with holocain, all with iridectomy except one, which was iridectomized the next morning on account of prolapse Holocain seems to me to be a more satisfactory anesthetic than cocain, and I think the first drop often does not produce as much irritation as the first drop of cocain The fact that it does not influence the pupil or corneal epithelium is an advantage

Another class of cases in which I have used it are those small but painful corneal abrasions, the type in which the cornea of the woman is wounded by the nail of the nursing child, and we know how painful they are Knowing that holocain has no effect upon the corneal epithelium, and that it has a germicidal action we feel no hesitancy in putting it into the hands of patients for as liberal use as they may require

I have noticed two things which I do not know whether to attribute to the drug or to my preparation of it One is that after standing for some time the solutions acquire a delicate pink color, not so deep as eserin, but a faint pink It may be that this is due to some action of the holocain on the glass bottle in which it is preserved The other point is that in one case of cataract extraction the solution which I had used repeatedly did not produce anesthesia Not being able to get a fresh solution at once, I had to use cocain I later operated upon the other eye of that patient with holocain, and with satisfaction

People frequently come to the occulist with a foreign body and ask me to "take this out without cocain if you can, because it dilates the pupil so I can not work the rest of the day" It becomes a satisfaction then to have such an anesthetic as holocain

Dr C D Wescott, Chicago—I have been using holocain solutions for six months, and have two observations to make that may be of interest in this connection To test the rapidity of the anesthetic action of a 2 per cent holocain solution I used it in an extraction After cleansing the eye I applied one drop on the cornea, waited one minute and gave another, in one more minute applied a third and immediately made my section without any sensation to the patient After completing the section I applied another drop, waited perhaps forty seconds and did the irridectomy without the slightest evidence of pain

I am inclined to think, however, from another experience that holocain is not absolutely without deleterious effect upon the epithelium In a nervous, hysterical woman, where I was obliged to do a very tedious advancement, the tendon having retracted very far, I used a 1 per cent holocain solution The eye was exposed for thirty minutes and although I applied boracic acid solution repeatedly, when I came to take out the speculum I noticed a positive blur of the corneal epithelium The diameter of this spot was at least 2 mm , and touching it very gently with a smooth instrument, I demonstrated beyond doubt that it was separated from the substance of the cornea I cleansed the eye, bandaged it and no harm resulted I operated upon the other eye of the same patient two or three weeks later, using 5 per cent cocain solution, without any deleterious effect upon the epithelium, but the eye was not exposed more than fifteen minutes in that operation

Dr F C Hotz, Chicago—We are indebted to Dr Randolph for having conclusively demonstrated by experiment that a solution of holocain is and remains sterile for an indefinite time It is certainly a most valuable local anesthetic It is the ideal local anesthetic for removing foreign bodies, and to have such a remedy that we can at a moment's notice use, with the knowledge that it will not carry infectious germs into the eye, is of great value It has been stated so frequently that I need not now go over my experience, to bring out all the points about holocain One point, however, that should be mentioned is this, that it irritates more than cocain and in fact increases the congestion of the eye, and on that account I have noticed that in muscle operations there is more hemorrhage than after the use of cocain To obviate this bleeding, I have first used cocain to produce anesthesia and then kept it up by means of holocain, for I find that it will keep up a continuous anesthesia for any length of time needed, if instillations be repeated about every five minutes

Dr Frank Allport, Chicago—I would like to ask Dr Randolph if the holocain solution can be boiled without any injury to its efficiency?

Dr Randolph—Yes sir

Dr H M Starkey, Chicago—I am sorry we have not had a little more discussion of the first paper, which is certainly a valuable contribution to the subject I think, as we make more careful examinations of the cases that come before us with regard to their bacterial infection, we shall be able to classify them in a more scientific manner The attention of the section is called to a ready means of obtaining pus from patients that we see outside of our office It used to happen to me frequently to be called to see a case of purulent conjunctivitis or other infection at the patient's house, whence I had no means of taking secretion back to the laboratory, and perhaps on making another visit the conditions were found to be so changed that it was useless to take the specimen It is now my custom to have a few cover glasses constantly in my pocket I carry these in a very small tin ointment box and also have another box of the same size in which to carry the infected covers to the laboratory In this way a small drop of secretion may be easily and safely carried between two covers

Dr R L Randolph, Baltimore—I have been very much interested in what has been said by those who have used holocain, particularly in Dr Ellett's remarks We meet with cases in which cocain acts in the same way and where a general anesthetic is called for It is of great value to know that this agent possesses properties that are not only antagonistic to the growth of organisms, but that they can not live in it, for it actually kills these organisms

---

FIVE CASES OF CONGENITAL, BILATERAL, SYMMETRICAL DISPLACEMENT OF THE LENS OF THE EYE IN THREE SUCCESSIVE GENERATIONS OF ONE FAMILY

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10 1898

EDWARD FROST PARKER, M D
CHARLESTON, S C

Cases of congenital ectopia lentis may, for convenience of reference, be divided into three groups first, those occurring in one member of the family, second, those occurring in several members of the same family, and third, those occurring in one or more members of a family for two or more generations

The malformation is not commonly met with, as out of fifty thousand hospital and private patients of Knapp's in New York City, only ten (1 in 5000) were seen Notwithstanding this, however, illustrations of individual cases (group I) are quite numerous in literature, and probably number about a hundred

Examples of the malposition occurring in more than one member of the same generation of a family (group II) are also on record to the number of twenty Instances of the ectopia in several members of the same family for several successive generations (group III) are quite rare and far more interesting, and merit reporting from this standpoint no less than from the fact that they show in a remarkable manner the marvelous and fateful power of hereditary influence in the transmission of physical defects, as well as disease

A complete record of all such instances I am enabled to report below, through the courtesy of Dr David De Beck of Cincinnati, a recognized authority on congenital anomalies, to whom I am much indebted

D'Oench[1] in 1881, presented some valuable conclusions as to the nature, history, symptoms, etc, of congenital ectopia lentis drawn from the collated statistics of most of the hitherto published cases, belonging to the three groups I have mentioned He relates that the first cases of luxation of the lens recorded were reported by Sichel in 1846, but that these were no doubt spontaneous, Sippell[2] in 1859, being the first to draw the distinction between congenital and spontaneous luxation, illustrating the same by reporting the condition in his own, his mother's and his brother's eyes The influence of heredity was quickly recognized, though the exact cause remained for some time a subject for theory

Lang and Collins[3] assert that it is "due to some defect in the development of the suspensory ligament, caused by a failure or late closure of the ocular cleft in the ciliary region, so that as the eye expands there is no suspensory ligament to hold the lens down in that region, and it consequently becomes drawn in the opposite direction"

Five cases of bilateral, symmetrical, congenital dislocation of the lens occurring in three successive generations of one family recently having come under my observation, I have endeavored to present their salient features in brief detail, and at the same time to collect the history of all similar cases

The following are my own cases

Mrs H, Columbia, S C, aged 67, consulted me Aug 12, 1896, and claimed to have had defective sight from her earliest childhood Her vision, however, in spite of great difficulty in getting glasses to suit her, had been useful until recently, when it had become smoky The eyes of her parents were normal as far as she knew She had six children, only four living By means of either focal illumination or the ophthalmoscope the dislocation of the lens could easily be detected, in the right eye almost exactly, but only slightly upward The right lens was completely and the left partially opaque With the instillation of homatropin nothing further was observed, no threads or suspensory ligament folds being found Gray tremulous irides Patient could read with R E [illegible]/200 + 8 D Sph — [illegible] J 14 at 5 inch + 16 D Sph — No 9 With L E [illegible]/200 no glass improves, J = 14 at 5 inches no glass improves

Raab[4] asserts that congenital ectopia is one of the most frequent causes of spontaneous luxation, and D'Oench corroborates this by stating that the number of cases in which both congenital and spontaneous luxation have been observed make it almost certain that the latter is a frequent result of the former I judge therefore that the luxation of the right eye was at first up and out, but that the same changes which caused it subsequently to become opaque caused it to change its position In addition downward luxations are rare and unknown She received convex glasses and was dismissed

Mrs A W, of Charleston, S C, aged 35, a daughter of Mrs H was seen Nov 8, 1897 Mrs W is very myopic, and wears glasses She has three children, two boys, one girl

Vision in R E = 15/40 not tested with glasses J = 1 at 6 inches L E = 3/200 not tested with glasses J = 5 at 2 inches Brown tremulous irides, upward dislocation of both lenses

Albert W, aged 15 Brown tremulous irides Vision R E 2/200 not tested with glasses J = 7 at 1 inch Left eye 15/200 not tested with glasses J = 1 at 6 inches Dislocation of both lenses upward and outward

Theodore W, aged 12 Brown tremulous irides Vision R E 15/30 J = 1 at 6 inches Does not wear glasses Vision L E 15/30 J = 1 at 6 inches Slight upward dislocation of both lenses

Mary W, aged 8 Brown tremulous irides Upward dislocation of both lenses Vision R E 3/200 J = 5 at 1 inch L E 2/200 J = 5 at 1 inch No glass improves

D'Oench thinks that in those cases where no glasses improve the vision it is due, perhaps, to a "torpor of the retina, caused by indistinctness and interference of the images"

The indisposition of the patients to submit to any prolonged examination prevents more exact observations as to the proper corrections of the errors of refraction

In all the cases, the irides were tremulous, the anterior chamber appeared deepened in that part unsupported by the lens, the lenses were clear, except in the case of Mrs H Their size was normal, the suspensory ligament was not observed, the direction of displacement was as stated, upward, and upward and outward, the intelligence was of a high order the vision varied with a degree of luxation the tension, the cornea, as well as the shape and size of the globe and the fundus and disc even were all normal, no diplopia was complained of and there was no corectopia, irideremia, mystagmus, coloboma, detached retina or strabismus observed, the dilatation of the pupil in the two cases in which a mydriatic was used appeared normal

The following is a resumé of similar cases on record

Morton[5]—Ten examples, presumably in five successive generations Father, two sons, grand-daughter, her three sons, two children of one of these and one child of another Direction of dislocation in nearly all inward and upward

Bresgen[6]—Ten examples in three generations Mother, two daughters, a son free, but his son affected, one of the daughters with all six children affected Direction in all upward and inward

Keyser[7]—Nine examples in three generations Father, daughter and three sons, and the daughter's three sons and a daughter Direction downward and outward

Williams E[8]—Three examples in two generations A father, son and daughters Direction not stated

Sippell[2]—Three examples in two generations Dr Sippell himself, his mother and a brother Direction not stated

Dixon[9]—Four examples in two generations Mother and three sons Direction, two upward and inward, one inward, one upward

Tiffany[10]—Eight exa [illegible] genera Father and seven of his [illegible] Directi [illegible] varieties represented

Wordsworth[11]—Six examples in three generations Mother, two sons and three grandchildren Direction in all upward and outward

Parker, E F[12]—Five examples in three generations Mother, daughter and three grandchildren Direction in all upward, or upward and outward

DISCUSSION

Dr W H Wilder, Chicago—I doubt if the time allowed us will be sufficient for all the work before the section and I think in this connection I will *briefly relate the cases of ectopia lentis* recorded in my paper A woman 39 years of age, came to my service in the Illinois Eye and Ear Infirmary, bringing her child, Maggie, 10 years of age, who complained of bad sight Examination showed a dislocation of the right lens outward and of the left lens outward and upward I examined the mother and found a dislocation of the right lens upward and outward, and of the left upward and inward I then had her bring all of her children for examination and two of the four living had dislocation of the lens The second child, Joe, aged 5 years, had both *lenses dislocated symmetrically* inward In all the cases the lenses were perfectly clear and transparent and the details of the fundus could be seen through the lens, or through the aphakic pupil In all the vision was considerably impaired and could not be improved by glasses, probably because the edge of the lens interfered so much

In all probability these are illustrations of dislocations occurring during three generations, because I found that this woman's mother was reported to have had very bad sight that could not be corrected by glasses

Dr Feanel B Tiffany, Kansas City—The Doctor has already referred to my cases and, as he stated, the displacement was upward and outward, except in one case, I think, in which the dislocation was inward As has been said, the lenses in these cases were perfectly transparent and when the pupil was dilated the vision was very much improved by glasses I recommended in these cases that an operation should be performed, the lenses to be removed, and I think the vision might have been very much improved if the operation had been performed and glasses adjusted, but I did not get the consent of these patients

Dr L W Fox, Philadelphia—I was very much interested in this report and I have just one thing to add, that is, concerning the difficulty in operating upon these cases Quite recently I attempted to perform one of these operations in the ordinary manner, but I found *it impossible to deliver the lens* in that way The fluctuation warned me that I should have a flow of vitreous and the lens would slip back, so I immediately took a Bowman scoop and delivered the lens

The peculiar formation of the lens was of interest A few years ago, you remember, I showed at the society four cases of black cataract In examining this lens I found it to bear the same characteristics In the course of time the patient had good vision with ordinary cataract lenses

Dr J E Minney, Topeka—I have had but one case and it was evidently *congenital*, though it was not seen until the lady was 35 years of age The dislocation in both eyes was downward and inward The vision could not be improved by glasses when I first saw her two months ago and I advised nothing else, as she had useful vision which enabled her to go about and do her housework Two weeks ago I operated upon her and instead of finding a lens I found a sac filled with whitish fluid I was determined to do something, and though I lost about one fourth of the vitreous I kept on until I got out that tough membrane On my way to this meeting I stopped to see that patient, but she did not meet me Her husband wrote that she was able to go out in the yard, could see the chickens and tell the difference in their sex, so she evidently had some vision

Dr H M Starkey, Chicago—I wish to report, so that it may go into the literature of the subject, some cases that I will publish more fully later on I had under observation a number of cases in one family, where I believe there was five children and their mother that had double ectopia lentis I showed three of the children and the mother at the Chicago Ophthalmological Society *Some of these eyes were highly* myopic, one requiring a 3 D or 4 D concave lens to obtain a good view of the fundus beside the lens

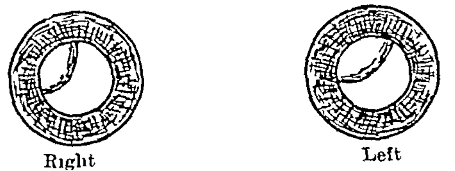
CASES OF HEREDITARY ECTOPIA LENTIS

Presented to the Section on Ophthalmology at the Forty ninth Annual
Meeting of the American Medical Association held at
Denver Colo June 7-10 1898

BY WILLIAM H WILDER, M D
Professor of Ophthalmology Chicago Policlinic Instructor of Ophthalmology Rush Medical College Surgeon and Pathologist to
Illinois Eye and Ear Infirmary Ophthalmic
Surgeon, Cook County Hospital
CHICAGO

The following interesting cases came under my observation in October, 1894, at the Illinois Eye and Ear Infirmary



Right Left

Fig 1—Mrs H, aged 39 years

Right Left

Fig 2—Maggie H aged 10 years

Right Left

Fig 3—Joey H, aged 5 years

Mrs John H, brought her daughter Maggie, aged 10 years, to the clinic because of poor eyesight, saying the child could not see well at school R V = 5/200, L V = 10/200, only slightly improved with a strong convex glass, + 12 D No concave glass was found that improved the sight

Examination revealed congenital dislocation of both crystalline lenses (Fig 2), the right being displaced directly outward to such an extent that its inner edge did not reach the center of the pupil, while the left was displaced outward and upward to nearly the same degree There was no opacity of the lenses and the details of the fundus could be seen either through the margin of the lens or through the aphakic pupil No sign of coloboma could be observed in any part of the uveal tract that was visible, nor of any other malformation or deformity, either about the eye or any other part of the body The child was well formed but mentally dull for her years

The mother, aged 39 years, then informed me that she herself had poor sight and was unable to get glasses that would benefit her Examination showed an ectopia lentis (Fig 1) The right lens was displaced upward and outward, the left upward and inward to about the same degree Both lenses were clear, as was also the pupillary space, so that the details of the fundus could be distinctly seen and no other deformities about the eye were observed R V =12/200, L V =5/200 Mrs H is a widow, born in Ireland, and has always been in good health Her father and mother are living in Ireland and are healthy She recalled that her mother had some defect of eyesight, she was very near-sighted and could not see small objects distinctly It is quite possible that she also has the same deformity She gives no history of syphilis and has had no injury of any kind She has four children living, three boys and one girl—our case—and four dead The living children are Maggie 10, John 7, Joe 5 and Tom 3 years of age

One boy older than Maggie died at 16 months, one child died at 3 weeks, one child between Joe and Tom lived 3 months and a baby younger than Tom died at 6 weeks

I told the mother to bring all her children for examination I found the eyes of John, aged 7, and Tom, aged 3, normal, and as near as could be determined with such young children, with normal visual acuity Joe, aged 5, however, showed the mark of heredity (Fig 3) Both lenses were symmetrically displaced directly inward, although not to the extent seen in Maggie's eyes The pupils were easily dilated with mydriatic, and as in the other cases, the lenses were clear and the interior of the eye, as far as it could be seen, was normal in appearance Vision could not be accurately tested, but seemed to be R =5/200, L = 8/200, with no marked improvement with glasses

---

AN ADDITIONAL CASE OF DOUBLE CONGENITAL MICROPHTHALMOS

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo June 7 10 1898

BY CASSIUS D WESCOTT, M D
INSTRUCTOR IN OPHTHALMOLOGY AT RUSH MEDICAL COLLEGE ETC
CHICAGO

During a trip in Minnesota last September, I was asked by my friend, Dr E J Lewis of Sauk Center, to see Maxwell James, aged 2 years, who was said to have been blind from birth

Upon examination the child seemed to be in perfect health and his development was good for his age I have been unable to secure a photograph showing the condition of the eyes, but the one which I present will give a general idea of the little fellow's appearance The lids and orbits were normal The palpebral fissure of the left eye was not smaller than usual, but the lids of both eyes appeared sunken Both eyeballs were smaller than normal, the diameter of the cornea measuring no more than 6 or 7 mm in left eye and 5 or 6 mm in the right The iris was present in the left eye, but the pupil was not well made out, because of a small central opacity of the cornea, and the fact that the opaque sclera seemed to shade off into the cornea, leaving a narrow ring of clear cornea between an outer opaque ring and a central circular opacity The right eye was decidedly smaller than the left There was almost no clear cornea, the iris showing faintly through the almost opaque membrane The movements of the eyes were normal, but limited No cysts could be demonstrated in either orbit and the conjunctiva was smooth and free and gave no sign of past inflammation There was evidently vision in the left eye, for the child could see to get about, and was immediately attracted by bright objects held before it

The baby had always been perfectly well and presented no other physical anomaly The parents were Americans of the middle class, and had always enjoyed good health They had the appearance of health when I saw them, but both were spare and the mother did not seem to be especially vigorous She had borne but two children, gestation being without incident and delivery natural in both instances, but both children had been born blind The first, a girl, had died at 18 months, of some acute infantile disease, but up to that time had seemed well and normal, except that the eyes were almost exactly like those of the little boy, whose case I have just described

A careful inquiry failed to elicit any cause for these two cases of microphthalmos in the family, and the parents had no theory to suggest So far as the mother knew, or would tell, nothing had happened during the intra-uterine life of the infants which might interfere with their development Although an itinerant professor had promised to cure the eyes of the little boy, for $50 cash, in advance, I gave it as my opinion that little change was likely to occur, although it might be possible to slightly improve the vision of the left eye by iridectomy, if it should increase in size with the growth of the child

Treacher Collins has reported ("Transactions of the Ophthalmological Society of the United Kingdom," Vol xiii) two cases of congenital microphthalmos, in which he secured specimens and made elaborate examinations He divides these cases into two classes First, those in which the eyeball is simply abnormally small, i e, very highly hypermetropic eyes, in which, beyond the defect in size, there has been no arrest in development Second, those cases in which the eyes, besides being small, have some other congenital abnormality, resulting from imperfect closure of the fetal ocular fissure This last class may again be divided into those where there is only a slight defect, and where the eyeball retains nearly its normal shape, and those in which the accompanying abnormality is very gross, the eye being usually exceedingly small, while connected with it are one or more cysts These cysts are often large, sometimes concealing the globe, which is situated at the back of the orbit, so that its presence can not be ascertained by clinical examination alone

His first case was of the class to which my own probably belongs, and I trust you will pardon me if I quote his report

> The patient was an infant who died when four days old, from congenital heart disease The aorta and pulmonary arteries formed one common trunk, and there was a defect in the ventricular septum The right eyeball measured 19 mm, antero posteriorly and laterally, and 8 5 mm vertically There was a small prominence in the sclerotic posteriorly, immediately below the optic nerve The iris was well developed, but several delicate fibers stretched across the pupil, evidently remnants of the pupillary membrane The ciliary body presented its usual appearance The lens was in its normal position and the vitreous appeared healthy The retina had

numerous little rucks in it At the seat of the prominence below the optic nerve there was a gap in the sclerotic, through which a fold of retinal tissue projected

Microscopic examination revealed no central blood vessel in the optic nerve The nerve fibers, after having passed through the lamina cribrosa, all sloped somewhat downward, the upper ones afterward curved backward to the upper part of the retina Below the optic nerve there was at first no retina, no uveal pigment layer and no choroid, only a mass of nerve fibers with fibrous tissue external to them This fibrous tissue, representing the sclerotic had, a short distance from the lower margin of the outer optic nerve, a break in its continuity Into the gap thus formed the nerve fibers passed, expanding somewhat after they were through it and becoming mixed with bodies like those found in the nuclear layers of the retina, external to this nerve tissue was a thin layer of fibrous tissue On the side of the gap in the sclerotic, farthest from the nerve, the retina commenced with its usual layers, being continuous with the nerve fibers emerging from the gap, around the edge of which, also, the uveal pigment layer turned The tunics of the eye were traced forward from the break in the sclerotic The retina was at first seen to possess its usual layers, the uveal pigment was present, also the choroid, which, however, was more cellular than normal and devoid of pigment A short distance farther on the choroid ceased and the uveal pigment layer became an unpigmented layer of cells

The left eyeball measured 18 mm antero posteriorly, 18 mm laterally and 16 5 mm vertically The cornea measured 8 25 mm latterly and 7 5 mm vertically There was a prominence in the sclerotic posteriorly, below the optic nerve, more pronounced than in the right eye There was a small coloboma of the iris downward The lens was situated nearly in the center of the globe, a considerable space being left between it and the posterior surface of the iris, it was almost globular in shape, measuring 5 mm antero posteriorly and 5 5 mm laterally The ciliary process, thin and much elongated, passed almost directly backward toward the sides of the lens In the center of the vitreous was a band of fibrous tissue, which passed forward from the back of the globe below the optic nerve to the posterior pole of the lens, this band was broad posteriorly and gradually tapered off as it passed forward Around this central band the vitreous appeared normal The retina had some small rucks in it Below the optic nerve, in the situation of the prominence seen externally, a fold of retina seemed to be included in a gap in the sclerotic

Microscopically the structure of the cornea appeared normal In the position of the coloboma of the iris the uveal pigment ended about on a level with the point of termination of Descement's membrane in the fibers of the ligamentum pectinatum The fibers of the suspensory ligament, passing from the much elongated ciliary processes, sloped backward and a little inward to the sides of the displaced lens, which was very rudimentary in structure The ciliary body, choroid, uveal pigment, and retina in the upper part of the eye appeared healthy In the lower part, the ciliary muscle was much elongated, and the choroid could only be traced backward as far as the equator of the globe, its posterior part being absent The uveal pigment layer, just previous to the termination of the choroid, was thrown into several folds, from this position it was continued backward, first as a layer of unpigmented cells, and afterward as tissue which looked like degenerate retina The band of tissue passing through the center of the vitreous was composed of bundles of nucleated fibers, with small blood vessels coursing among them, it was adherent posteriorly to the sclerotic, and anteriorly, where it was very thin and reduced to but a few fibers, it joined the posterior capsule of the lens The vitreous was continuous with it at the sides There were no central blood vessels in the optic nerve, all its fibers, after passing through the lamina cribrosa, bent directly downward, the upper ones curving round again to the retina above, which began in a fold The lower ones seemed to end abruptly at the band of fibrous tissue which passed forward through the vitreous Below this band of fibrous tissue some very degenerate looking retina, consisting mostly of nuclear bodies, was seen embedded in a gap in the sclerotic The retina in the lower part of the eye had its inner granular separated into two, some fibers separated by spaces running transversely between them

Hirschberg reports (*Berliner Klin Wochenschrift,* 1870) the case of a girl of three months, with double microphthalmos She was well developed, but her eyeballs, though well formed, were very small The horizontal corneal diameter on both sides was about 5 or 6 mm There was coloboma of the right iris, below and inward, and persistent pupillary membrane In the left eye there was luxation of the opaque lens downward, and a persistent hyaloid artery The fundus showed an extensive discoloration (coloboma) The child continued to develop and the eyes grew somewhat larger, but no perception of light could be discovered The parents were perfectly healthy

Rindfleish described (*Archiv f Ophthalmologie,* Leipsic, 1891) a case of bilateral microphthalmos, with cystic posterior ectasia, complicated with hydrocephalus The ventricles were dilated, the cerebellum was cystic and the hemispheres of the cerebrum were separated from the cranium by a collection of subarachnoid fluid The irregularities of the base of the skull had been obliterated by internal pressure The roofs of the orbits were concave upward, and the orbits thus depressed contained microphthalmic eyeballs, with connecting cystic structures

Williams of Boston has reported (*Boston Medical Journal,* 1850, Vol xliii, page 421) a case of microphthalmus, complicated with congenital cataract of both eyes, in a boy 13 years of age The entire globe was extremely small, and much sunken in the orbit The iris, in both eyes, was hardly more than half the average size in a new-born infant, the pupil scarcely larger than a mustard seed The entire field of the pupil in the right eye was occupied by a cataract, apparently formed by the capsule only, the lens having been absorbed The pupil of the left eye presented an opacity covering nearly its entire area, but a small point existed toward the temporal side, which was not occupied by cataract, and the opacity was less white than in the right eye Dr Williams successfully operated upon the cataracts, but with what result as to vision I am unable to say

Bernheimer reports (*Archives of Ophtholmology,* 1894) a remarkable case of hydrocephalus internus, in which the eyes of the patient were normal in external appearance, but very small The muscular and lachrymal apparatuses were normal in both The left pupil was not circular The axis of the left eye measured 12 mm, and lying to the lateral side of the optic nerve was a cyst 6 mm long, filled with clear fluid The right eye was continued posteriorly in a thick stalk, and was about the size of the left In place of the nerve was a sheath containing but a single vessel, and to its lateral side was a cyst continuous with the posterior and inferior portion of the ball The lens was small, egg-shaped and cataractous The retina was completely detached and much folded The optic nerve had a peculiar appearance, and nerve tissue could scarcely be found A third of the nerve tissue was converted into an egg-shaped cyst, communicating by a narrow cleft with the cavity of the eyeball The pigment epithelium and the choroid were normal and in position Near the choroidal ring the choroid was somewhat thickened and choroidal pigment was traced back to the wall of the cyst

FitzGerald reported (*British Medical Journal,* 1886, Vol ii, page 1385) a case of double congenital microphthalmos to the Royal Academy of Medicine in Ireland, and exhibited the patient There were two undeveloped globes, with cornea and iris, but little or no anterior chamber, illumination of the fundus was impossible The father of the child thought it could see when light was brought into the room, but after having several times made trial with both lamp and ophthalmoscope, Dr FitzGerald was unable to satisfy himself that the child saw anything The mother in this case gave a history of a fright during gestation, but at what period was not stated

Brailey reports (Transactions of the Ophthalmological Society of the United Kingdom, Vol x, page 139) a case of double microphthalmos, with defective development of the iris, in a patient with imperfect teeth and arms, seen at Guy's Hospital Vision of the right eye equalled fingers at 10 feet, and the field was much narrowed all round Tension was +1 and the eye was myopic about twelve diopters Vision was not improved by lenses The cornea was small, about 9 m m in diameter The iris was absent except a narrow crescentic piece in the inner side, which occupied about two-fifths of the circle The lens was in situ Its diameter seemed to equal that of the cornea The disc was cupped and had a myopic crescent to the outer side, and opaque nerve fibers to the inner side Vision of the left eye equalled fingers moving Tension was +2 and the eye was myopic The cornea was the same as in the right eye The iris was wanting except for three small isolated bits with rounded edge, situated on the inner side of the vertical line The disc was cupped

De Vincentiis of Pavia, reports (*Ann di Ophth*, Vol xiv) a case of congenital bilateral microphthalmos, with defective development of the heart Mayer described a case of microphthalmos with cysts in the lower eyelids Ginlini reports (*Ztschr f Vergleich Augenh*, Wiesbaden, 1891) a case of double congenital microphthalmos in a dog four weeks old Holtzke (*Archives of Ophthalmology*, Vol xii) made careful studies of the eye of a rabbit with coloboma of the iris, ciliary body and choroid, and general microphthalmos He closes his report as follows "The explanation of the above described changes is very simple There have evidently been extensive inflammatory processes in the eye, and I see no reason why we should not adopt Deutschmann's view (*Klin Monatsbl f Augenh*, March, 1881) that the arrest of development is only a changed development of the eye in consequence of an intra-uterine inflammation This inflammation has probably taken place in the latter half of the third week, the fetal fissure was nearly closed, or after having been closed, was again opened, the iris, on the other hand, had not begun to develop Why this inflammation was just at this fissure, which is so important for the development of the eye, can not be decided, unless it was favored by the greater vascularity of this neighborhood '

Hess reports (*Archiv f Ophth*, Bd xxxiv) and gives details of the microscopic examination of a series of microphthalmic eyes with colobomata he found in his cases no sign of past or present inflammation and concludes that it has very much less to do with the production of congenital malformation than is generally assumed

As I have no specimen to present, and have had no opportunity to make pathologic studies of microphthalmic eyes, I have no theory to offer as to the causation of these anomalies The appearance of the eyes in my own case would cause one to think immediately of an inflammatory process

31 Washington St

DISCUSSION

Dr Casey A Wood, Chicago—I have had personally no experience in these cases outside of some studies that I made with Mr Lang of London a number of years ago, when an attempt was made to show that cases of true anophthalus, one of the divisions of microphthalmus, was not possible As was declared some years ago, careful dissection will discover some parts of the eye and in considering the embryology of the eye it would seem strange to think that entire absence of the eye was possible The experience we had seemed to prove that we only have cases of true microphthalmus to deal with and that there is always some trace of the ocular structures to be found in the cranium

---

EXPERIMENTS IN THE USE OF ALUMINIUM FOR ARTIFICIAL VITREOUS

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo June 7-10 1898

BY D C BRYANT, M D

OMAHA

Some two years ago, after experimenting with several other kinds of material for an artificial vitreous, I commenced the use of aluminium for this purpose, and so far have met with nothing but very satisfactory results in its use In the beginning of my experiments a complete hollow ball was used, and the results were about the same as are secured by the use of the glass ball, that is, good results in a majority of cases, with an occasional case in which, sooner or later, the ball was extruded The fact that this unfortunate result would occasionally occur, led me to try the experiment of using a frame instead of a complete ball, allowing the cavity to fill up with granulation tissue These experiments were carried on with dogs, and proved fairly satisfactory, the failures, when they did occur, being due to infection, which is very difficult to avoid when the subject is a dog After allowing the frame to remain in the place for from six to ten weeks, the dogs were killed and the new stump examined The frames were found to be partly or wholly filled with new-formed tissue, and a slight amount of tissue drawn in from outside The frames, which were allowed to remain in place ten weeks or more, were practically completely filled, though in none of them had new tissue formation entirely ceased Through the kindness of Dr J S Foote, Professor of Histology and Pathology in Creighton Medical College, I am enabled to give a report of the result of a microscopic examination of the contents of one of these frames, which had remained in position eight weeks The report is as follows

Having completed the microscopic examination of the contents of the metallic eyeball which you presented, I submit the following report After cutting the ball in two, transversely, sections were taken, cutting from the metallic rim to the center of mass Beginning at the outer side of the specimen there are to be found the following areas 1, a layer of new connective tissues, in which are a great number of incompletely developed cells and new blood vessels 2, bundles of striped voluntary muscle running perpendicularly to the general direction of the fibers of the mass within The muscles are not new, and between them are found leucocytes The muscle is attached to the main mass by a connective tissue layer which is vascular 3, a layer of connective tissue fairly well developed, in which are many blood vessels and spindle, branching and irregular cells Intercellular substance complete 4, a dense area of blood capillaries, between which are many new embryonic cells 5, an area of delicate new connective tissue, in which the cells are the most *prominent* part, and the wavy character of the intercellular substance is less apparent than in the adult stage 6, an area of blood vessels and new embryonic cells, exhibiting elongation in one or two directions characteristic of a developing connective tissue Intercellular substance not developed From the above it would appear that the contents of the metallic eye ball are made up of tissues drawn in from the outside and hence, adult in character, and tissue generated from within, and, therefore presenting the phases of new tissue development.

This report of Dr Foote's corresponds with the macroscopic appearances presented by these stumps after removal There is always more or less drawing in of the surrounding tissues, while the main part of the cavity is filled with apparently new tissue I have used the frame in sixteen and the complete ball in four cases in human beings Three fourths of these cases were such as to require, from one cause or another, an enucleation instead of evisceration In the cases of *enucleation* there was little more reaction than follows the ordinary enucleation, the recoveries being quite rapid, without complications whatever In the eviscerations the healing process was considerably prolonged, in one case extending over three months before all irritation had subsided In all of the cases where the frame was used, everything has gone all right so far, there having been no after-trouble, *no tenderness or irritation* in the stump, and each patient wears an artificial eye with perfect comfort In one of the cases in which the ball was used, after evisceration, the patient returned a year after the operation, reporting that the ball came out about ten months after he was discharged from hospital

I am fully aware that the short time, the few experiments and the small number of cases reported here, do not prove that there are not serious objections to the use of the aluminium ball or frame but the results are good enough, I believe, to warrant the continuance of their use until such objections, if they exist, become manifest The aluminium has two qualities superior to glass, being both lighter and stronger Other things being equal, these two qualities alone would make it preferable to glass, either in the shape of ball or frame For the frame, I think it can fairly be claimed that if once healed in and filled with connective tissue there can be little or no danger of its sloughing or popping out, as will happen occasionally with the ball, whether it be of aluminium or glass The frame as used by me now is made up of a ball with a complete front and fenestrated sides and back These, of course, can be of any size to suit the individual case The technique of the operation and after-treatment, whether the case be one of evisceration or enucleation, is the same as when the glass ball is used, so no time will be used here in their description The one thing that I would insist upon, in the after-treatment, is the free and prolonged use of cold applications

DISCUSSION

Dr W L Fox, Philadelphia—There is one point in Dr Bryant's paper that I did not understand, that is whether these balls are used only in implantation or also in evisceration

Dr Bryant—I have used them both ways

Dr Fox—The point at issue is this, that in proper evisceration I fail to understand how new formed tissue could find its way into these balls, for in the proper Mule's operation the margins of the sclerotic are brought so well together that they close up and become a solid mass I am glad the Doctor has brought up the question of implantation, for I consider it one of the greatest advancements in ophthalmology Every ophthalmologist finds ten or twelve years after enucleation a cicatricial contraction of the tissues of the orbit, and there I have found the implantation of great value In a case reported two years ago I implanted a glass ball where I could not think of anything else to do do, and it proved to be sufficient to hold the artificial eye and pleased the patient so well that I was led to continue the operation So, today where by any chance I am obliged to enucleate I immediately put in a glass or silver ball I have found that in nearly every operation we can succeed in making a good artificial stump and it is wonderful what excellent movement follows It is not as good as the Mule's operation, but it is of great value, for it fills out the artificial eye and the secretions are not retained in the sac but are thrown off, and for this class of patients it produces a heaven on earth

In an article which will be published shortly in the *International Clinics*, to illustrate the position the glass ball attains I have had these X ray photographs taken (exhibiting skiagraphs) I want to encourage the gentlemen of this Section to try two things, first, the Mule's operation, and second, the implantation You will have some difficulty at first in the technique I am not perfect in it myself, though I have done 125 operations I have lost four cases, that is, the glass balls came out, and why I can not tell Instead of using a No 4 silk I now use the most delicate silk, the 0 or 00, and I believe it the best Immediately after the operation I saturate a piece of cotton with 1 to 500 chlorid solution, bandage that over the eye and do not open it from forty eight to seventy two hours At the end of that time there will be a slight excoriation of the skin but no pus and no reaction, with positive success

Dr W Montgomery, Chicago—I would like to ask Dr Fox what his preference is, in implantation, between glass and silver balls?

Dr Fox—I have no preference whatever and it is simply a question of expense to the individual, as the silver balls cost $1 75 and the glass balls 5 cents I think it is almost impossible to break the glass balls, for in one of my cases a boy was struck in the eye by a cow's horn and the ball did not break Unless, then, a bullet be shot into it I think it would be practically impossible to break the glass ball

Dr W H Wilder, Chicago—I would like to ask Dr Fox, who has had so much experience in this matter, whether or not in following up any of these cases of Mule's operation he has had any cases of sympathetic ophthalmia, or has known of any that have occurred?

Dr Fox—I have not had a single case of sympathetic ophthalmia, and I may state here that I have had recently two or three very interesting cases In one there was evidence of sympathetic ophthalmia beginning—the ciliary injection, the keratitis punctata and the dimness of sight all being present I saw in that case that the fight was on, and it was just at that point where it required a great deal of bravery on my part to do a Mule's operation I remembered that Carter of London had had a similar case and I settled the question by following him and performing the Mule's operation In justice to a brother practitioner I must say that he had seen the case and had already started in with heavy doses of mercury, so it may be that the case was at that time on the turn At any rate three days after the operation the symptoms of sympathetic inflammation had disappeared in a measure and the patient continued to improve I continued the mercury treatment, of course, giving inunctions as well as 1/10 of a grain calomel three times a day In another similar case, but not so pronounced, I performed the Mule's operation and the symptoms disappeared So these two cases convinced me that I need not be afraid to perform this operation even when sympathetic symptoms are already present

Dr Harold Gifford, Omaha—It does not seem to me that the distinctive features of Dr Bryant's balls have been sufficiently appreciated This framework gives a hold for the sclerotic, as it contracts down and is much less likely to be expelled than a complete sphere I can claim a slight share in this improvement, because when Dr Bryant first used aluminum he had ordinary spheres made, but complained that he could not get them made without a hole in them It occurred to me that the hole might be a good feature and I suggested that it might be a good plan to have more than one hole made for the tissue to grow into

Dr Bryant—Dr Fox has the advantage of us in the wild and woolly West in that he has seen many more cases The most of my cases are seen in working men injured in the railroad shops of my own city, and in the usual year we have perhaps ten to twenty cases That is all that I have had the chance to see in the last two years The aluminum ball has the advantage over the silver in that it costs only 4 cents unpolished, and a few cents more for the polishing It is even lighter than the glass ball and is stronger

---

GONORRHEAL CONJUNCTIVITIS AND IRITIS

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10, 1898

BY FRANK S MILBURY, M D

OPHTHALMOLOGIST, OTOLOGIST AND LARYNGOLOGIST TO THE BEDFORD DISPENSARY AND HOSPITAL AND THE NORTH BROOKLYN EYE EAR AND THROAT HOSPITAL
BROOKLYN N Y

Gonorrheal conjunctivitis, or gonorrheal ophthalmia is one of the most serious inflammations met with in the eye It in produced, usually, by the direct transmission of pus from a gonorrhea into the conjunctival sac It finds its way to the eye from a urethral or vaginal gonorrhea, or from a similar inflammation in some other eyes, so that the inoculation may either be from the individual himself, as is most commonly the case, or by some one else whose towel has been soiled by the discharge and used subsequently by the patient Such pus is known to acquire its virulence from the presence of characteristic micro-organisms to which the name of gonococci is given

The first symptoms may begin within from two or three hours to three days after inoculation The appearance during the first day may be such as to suggest merely an acute attack of simple conjunctivitis More frequently the rapidity with which the symptoms set in, and especially the early appearance of more or less chemosis, excites suspicion, and leads to the detection of the source of inflammation Considerable differences exist in the length of time before the inflammation reaches its full height and leads to a copious purulent discharge What is usually distinguished as the first stage, in which only a watery and slightly mucoid discharge—often considerable in amount — takes place, may last a couple of days or more, or may rapidly pass on to chemosis, due to a fibrino plastic exudation beneath the conjunctiva and to intense redness and swelling of the lid In the most severe cases the infiltration of the conjunctiva is so great that the latter in places appears no longer red, but grayish-yellow, because, as in diphtheritic disease of the conjunctiva, the vessels are compressed by the bulky exudation, and the conjunctiva is thus rendered anemic The conjunctiva forms a tense, grayish-red wall about the cornea Quite often the surface of the conjunctiva is found to be covered with clotted exudate like a croupous membrane The secretion produced by the conjunctiva is like meat-juice, that is, it is a serum which is colored by admixture with blood, and in which float some flakes of pus

The eye is uncommonly sensitive to contact, the lymphatic gland in front of the ear is swollen, and there is some fever and pain, burning and neuralgic in character, photophobia and lachrymation are constant, and increase as the tension of the swelling of the conjunctiva and lid becomes greater The swelling of the upper lid generally reaches such a degree as to cause it to hang down over the lid, and to assume a red, glossy appearance on its surface It is then perfectly impossible for the patient to open his eye, or even to raise the lid to any extent with the finger The full height of the inflammation is generally sustained for from one to three days, after which the swelling begins to diminish and the lid regains some of its natural wrinkling, and the circulation in the conjunctiva becomes freer Simultaneously with this there begins a very profuse secretion of pus, which strikes out continually from the palpebral fissure

In the further course of the disease the swelling of the conjunctiva keeps constantly diminishing, the eye in many cases returning to the normal state within the next four or six weeks In most cases, however, a condition of chronic inflammation of the conjunctiva remains, which is designated as the third stage of the disease—the stage of chronic blenorrhea

Some cases—and often, it would appear, the less severe ones—in which the palpebral conjunctiva is much more affected than the ocular, so that the absence of marked chemosis renders corneal necrosis much less imminent, gradually lapse into a chronic state In these cases the conjunctiva often remains enormously swollen for months, the tarsal portion assuming a thick and more or less velvety appearance, while the retrotarsal folds present large fleshy elevations and furrows, which protrude into prominence when the lids are everted Not infrequently this leads to ectropion The lower lid is more often ectropic, doubtless on account not only of the smaller size of the tarsus, but also on account of the thickening of the skin produced by excoriation by the overflowing tears and secretion Occasionally, however, the upper lid is everted as well, the everted portion being hardened and encrusted if not properly attended to

The most dreaded complication of blenorrhea is the involvement of the cornea, by which, in many cases, incurable blindness is produced At first the cornea becomes dull and covered with a slight diffused opacity Then circumscribed infiltrations of grayish color make their appearance, which soon become yellow and break down into ulcers These infiltrations may be situated at the margin of the cornea and may give rise to a speedy perforation of the latter, and this may prevent the destruction of the whole cornea In some cases, however, these infiltrations may form a ring around the cornea and become confluent, producing thereby an annular abscess In that event the cornea is lost, for this ring soon spreads over the whole cornea and destroys it, which usually happens in the most severe forms Sometimes corneal ulcers are not developed until late in the disease, when the blenorrhea is well on the retrograde path

The prognosis of the affection depends upon the condition of the cornea and the severity of the case

Treatment —First, the great importance of warning patients suffering from gonorrhea, or, in the case of women, from any other discharge as well, of the danger to their own eyes and to those of others living in the same room, in using towels, sponges, etc , in common, and of the consequent necessity of absolute cleanliness can not be exaggerated One of the most important conside[illegible]s when only [illegible] is affected—and t[illegible] is the [illegible] to protect the [illegible]atio always be done by tying it up in the following way The lids are gently closed and kept so by two or three strips of courtplaster The hollow between the nose and eye is then filled up with absorbent cotton, over this a piece of guttapercha tissue is placed and the whole bound down along the edges with strips of closely-fitting adhesive plaster

Special care must be taken that this adheres well along the nose, and the patient when in bed should lie as much as possible on the side of the affected eye, to prevent the discharge from trickling over to the other side and possibly loosening the plaster, if it is properly applied there is, however, not much fear of this Before tying up the sound eye it is well to thoroughly wash it out with an antiseptic solution of corrosive sublimate, 1/6000 to 1/4000 In this way the effect of inoculation, which may have taken place shortly before the patient seeks advice, may in some instances undoubtedly be neutralized

It is certainly very trying for the patient to have the good eye occluded from vision at a time when the other, owing to the great swelling of the lid, is temporarily useless He is thereby rendered very helpless and unable to go about alone, so that his spirits, generally depressed as he is, are not raised by his being put entirely in the dark On this account it is well, where this is possible, to protect the sound eye in a manner which does not altogether interfere with its use This may be done by strapping a small watch glass over the eye Dr Buller's method This plan has the advantage of allowing one to observe the sound eye all along, and therefore the shield can be left on continually, whereas the ordinary occlusion bandage has frequently to be reapplied After this is done we turn our attention to the inflamed eye The treatment to be adopted will depend on the stage of the inflammation and the state of the cornea When the discharge is only serous and the chemosis slight, pretty frequent washings with corrosive sublimate solution (1 in 5000), and ice compresses, frequently changed, may be used, and the patient's room well ventilated and slightly darkened When the inflammation comes to its acme, ice may be discontinued, and nothing used but the antiseptic wash and a little vaselin smeared along the edges of the lids Local bleeding is recommended, but it is of doubtful use, still, it may be tried The method generally in use is to make a large cut across the outer canthus with a pair of scissors This at the same time tends to relieve the tension of the swollen lid on the eye At this stage it is almost impossible to evert the upper lid, so that any attempt at the local application of caustic solution is neither desirable nor always possible The cornea must be cautiously watched, and any symptoms of loss of vitality counteracted, if possible, by free incisions in the chemosed conjunctiva However, this treatment is not always efficacious in arresting the dreaded complication, owing not only to lack of nutrition by pressure on the anterior ciliary vessels, but to actual stasis in them As soon as the upper lid can be everted without much difficulty, an application of nitrate of silver (5–10 grains to 1 oz) should be made once or twice during the twenty-four hours, with the object of restraining the discharge and reducing the risk of subsequent inoculation of the cornea Any ulceration of the cornea appearing at this stage may be treated by applying directly to it the same caustic solution, unless it has begun to heal, when care should be taken that the nitrate of silver does not come in contact with it Free exercise in the open air is desirable Atropin to relieve congestion, the bowels kept free, good diet, and opiates when sleep can not otherwise be obtained, constitute the treatment

Gonorrheal iritis develops in those cases in which gonorrhea has given rise to a general infection, it is closely allied to rheumatic iritis, but is an exceedingly rare form The inflammation is always severe, and the cause, owing to coexisting inflammatory changes in the joints, is apt to be overlooked Gonorrheal iritis always seems to occur in both eyes, though not always quite simultaneously, and it may be with different degrees of severity in the two eyes Successive attacks of gonorrhea are sometimes accompanied each time by iritis, and in other cases, although no fresh inoculation takes place, a return of the joint affections may be accompanied by a recurrence of the iritis as well The local treatment is the same as for other forms of iritis Potassium iodid in large doses seems to be the best general treatment at first, followed, as the inflammation subsides, by quinin and iron

GENERAL VIEWS

As we employ perineorrhaphy to repair uterine prolapse (sacropubic hernia) as well as deficiency of the external sphincter apparatus, the subject covers a vast field All kinds of genital supports—peritoneal, fascial and vaginal sphincter apparatus—must be considered To have prolapse, both peritoneal and fascial supports must yield, as well as the occurrence of muscular relaxation No one support to the exclusion of all others can be claimed for the uterus

The utero-rectal (sacral) ligaments which consist of peritoneal duplicatures, containing fibro muscular tissue, are very efficient uterine supports The peritoneum itself, on account of its intimate connection to the pelvic viscera and fascia, doubtless gives considerable support

The round ligament, with its peritoneal duplicature, the broad ligaments holding some muscular fibers, and the vesico-uterine ligaments all assist in supporting the genitals In the consideration of sacropubic hernia, the intra abdominal pressure, the state of the abdominal walls, as well as the visceral supports, should be weighed Whether the patient has enteroptosis is a very significant question The peritoneal duplicatures, with their contents, constituting mesenteries of the genitals, elongate in enteroptosis just as they do with the stomach, kidneys, intestines and other viscera It is not uncommon to find a uterus excessively mobile, due to relaxed supports Displacements of the genitals not only involve their special supports and the pelvic floor, but the whole peritoneum and the abdominal walls

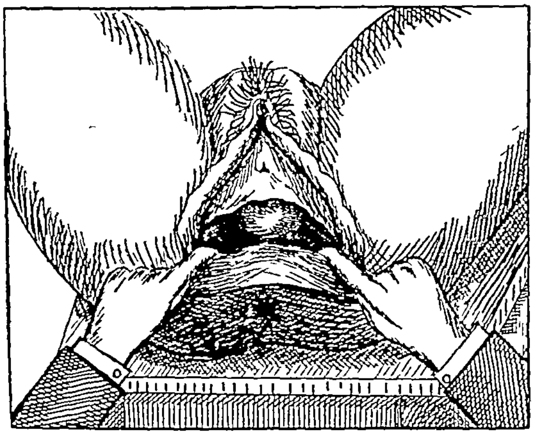

Fig 10 —(Robinson Scholer) A medium degree of relaxed vaginal outlet, to be remedied by colpoperineorrhaphy

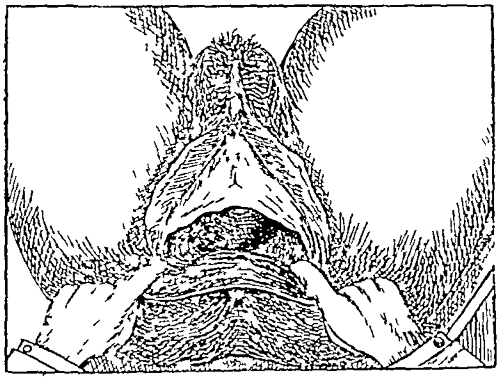

Fig 11 —Robinson Scholer) A high degree of relaxed vaginal outlet to be remedied by colpoperineorrhaphy

It need not be doubted that the mechanism of the pelvic viscera is complicated The levator ani, closely ensheathed in its superior and inferior fascia, forms a diaphragm through which the viscera find an outlet By introducing the finger three-fourths of an inch into the vagina, the ledge made by the fascia and muscle enclosing the vagina can be distinctly felt The muscle normally ensheathed in its scabbard, drives the vagina and rectum directly forward and upward toward the pubic arch The fascia inserts itself into and embraces the lower third of the vagina and is the important support The levator ani (fascial and muscular) supports lend to the lower third of the vagina a firm fixation, quite immovable, forcing its walls closely in contact for about an inch, producing a pronounced vaginal sphincter apparatus In marked contrast to the lower third of the vagina is the upper portion, which is lax, mobile and yielding, being surrounded by loose connective tissue only The urethral portion of the vagina and the neck of the bladder are firmly fixed by the vesicopubic ligaments which dwindle off into the white line This can be seen during respiration with highly relaxed and displaced genitals, the urethro-vaginal portion remains still, while the remainder of the organs move to and fro with each breath or diaphragmatic movement Superiorly the lower vagina is extremely firmly fixed by the three layers of firm, fibrous fascia —the posterior layer of the triangular ligament, the anterior layer of the triangular ligament, and the deep layer of the superficial fascia These three powerful and dense fibrous layers originate at the margins of the ischiopubic rami and stretch across the arch of the pubis, surrounding the vagina and being intimately blended in the vaginal walls To be convinced of the fact that these fibrous laminæ are the all-important supporting structures that not only retain the lower end of the vagina in position but prevent it from being torn away at labor, one needs only to dissect away all supports from the lower vagina except them, and then by tugging and dragging on the inlet of the vagina, note their almost unyielding qualities Parts of these fibrous layers (triangular ligament) are frequently lacerated in labor, and must be included in the flap-splitting and deep sutures to restore the lower vaginal tube

Laterally, the vagina is firmly fixed against the descending rami of the pubes, not only by the so-called triangular ligament, but by the levator ani fascia superior and inferior enclosing the levator ani muscle By introducing the finger for about an inch into the vagina and palpating the posterior and lateral parts, one can feel a blunt band running from the pubic ramus on each side downward and uniting behind the vagina in a still thicker and more blunt band This is the free edge of the levator ani and its double fascia, where they come in contact and embrace the vagina The vaginal canal, below the free edge of the levator ani and its fasciæ, is directed forward by the perineal body and triangular ligament while the same body directs the rectal canal backward

The lower third end of the vagina is quite thick, very vascular possesses turgidity and is surrounded by some circular fibers In short, the lower third of the vagina possesses a distinct, vigorous sphincter apparatus which plays an important rôle in the support of the sexual organs and in perineorrhaphy

In making a division of the supports of the pelvic viscera into those of the peritoneum and those of the sphincter apparatus, we may first make a few remarks on the deficiency of the peritoneal supports The utero-rectal (sacral) ligaments (extending from the rectum to the neck of the uterus) are the most important of the peritoneal supports If they relax, the cervix will pass downward and forward, while the body and fundus of the uterus will pass backward In other words, elongation of the sacrorectal ligaments is the initial stage of retroversion and descensus Retroversion changes the intra-abdominal pressure from the posterior surface of the uterus to the anterior and superior After retroversion the intra-abdominal pressure is exercised on the top and anterior surface of the uterus, driving the pointed neck, like a conical wedge downward at every breath The cervix acts in retroversion as a wedge or cone, and gradually forces the sphincter apparatus to yield The filling bladder forces the fundus backward and the full rectum pushes the cervix forward, all perfecting the retroversion, the beginning stage of prolapse, by elongating the utero-rectal ligaments

In colpoperineorraphy we must not only repair the deficient sphincter apparatus, but the cone shaped descending cervix must be amputated and its blunt end turned downward, so that it should point and rest against the sacro-coccygeal region (bone and ligaments) instead of attempting to dilate the levator ani muscle at every breath by the change of intra abdominal pressure When the cervix once gets firmly into the vulva, i e, into the vaginal sphincter apparatus, the descent is rapid and inevi [illegible] h [illegible] er two thirds of the vaginal walls being loose, easily descend with the uterus In descensus uteri, the vagina is inverted, showing in all probability that intra abdominal pressure had displaced the uterus first in the process of descent An intact sphincter apparatus will long retard a descending uterus The anterior vaginal wall appears first in prolapse, however the vesicopubic ligaments may still retain the bladder in position Posteriorly, the peritoneum descends with the cervix and upper portion of the vagina In other words, the upper part of the rectum and vagina are separated, while the lower rectum and vagina are closely connected by a musculo-fascial septum, with the thin edge of the wedge upward

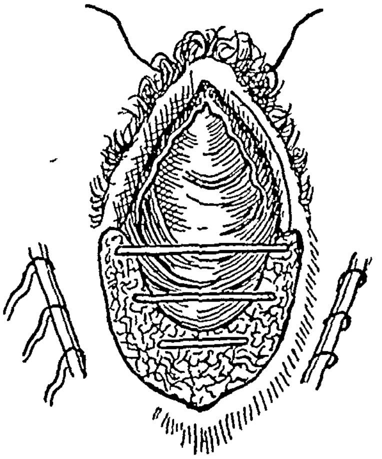

Fig 12—(After Hegar and Kaltenbach) Baker Brown's method about 1850

Rare forms of prolapse may occur where the cervix is elongated or where the peritoneum is loosened and stretched Space forbids reference to many other conditions and kinds of peritoneal supports

GENERAL VIEWS IN THE DEFICIENCY OF THE SPHINCTER APPARATUS

The vagina should engage more of our attention, because it is on this apparatus that the operation of colpoperineorrhapy is applied The primary factor which produces deficiency in the supports of the sphincter apparatus is labor Other factors play but a secondary rôle

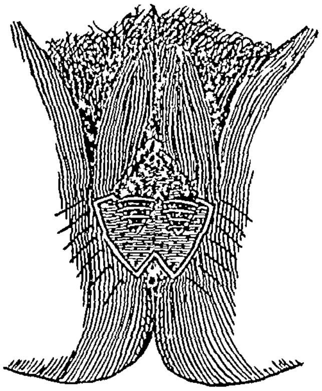

Fig 13—Dr Goodell's method of colpoperineorrhaphy

The pelvic fascia is not infrequently lacerated near the ischiopubic rami, where the fascial sheath is ruptured the contained muscular fibers also suffer laceration The results are cicatrices and loss of substance, which may be felt by palpation The anterior vaginal wall generally escapes laceration, but the posterior vaginal wall is often damaged, showing various sized and formed lesions Relax action is prominent and closure incomplete Instead of the curved lower canal with the perfect sphincter apparatus, there is a patulous, relaxed, open mouth, resembling a tobacco pouch which has lost its puckering string Sometimes the vaginal mouth is closed by an anterior and posterior vaginal fold, for a considerable distance up the vagina The causes of displacements of the sexual organs are so numerous—as elongation of the utero rectal ligaments, elongation of the cervix, laceration of the levator ani fasciæ, muscles and triangular ligament, intra-abdominal pressure, enteroptosis—that all possible factors must be considered in repair Repair must consist in correcting vicious forces, as the pointed cervix should be amputated and turned backward, the posterior vaginal curve should be restored with a perineal body to turn the rectal end back and the lacerated levator ani fascia should be reunited

An analysis should be made of the factors producing displacements and lacerations in the genital organs Deficiencies of peritoneal support should be considered distinctly from deficiencies of the sphincter apparatus, however, the both may be often combined Yet, after all, our chief attention will be directed to deficiencies of the sphincter apparatus, for on it depends prolapse and lacerations, chiefly arising in it Deficient primary peritoneal supports give rise to vaginal inversion as rectocele, vesicocele, bladder and rectal disturbances, and the vaginal mouth loses its puckering string condition In coloperineorraphy, the whole of the tissue of the pelvic floor should be utilized for support by forcing it into the median line This will rest over the tonicity of the pelvic floor and form a firm cicatrix which will prevent sacro pubic hernia and also reproduce the normal curves of the canals To accomplish this, extensive denudations or flaps are requisite

Successful colpoperineorraphy must make the pelvic floor as tense as possible and the newly formed cicatrix will aid materially in its success The thickened tissue (columns) on the anterior and posterior vaginal walls are remnants of Miller's ducts, which should be and are preserved in both Dr Emmet's and Mr Tait's flap operations They furnish evident support from their fibrous masses It may be observed that nearly all successful methods of perineorraphy make the denudations in the vaginal sulci on each side, and avoid sacrificing the thickened tissue on the anterior and posterior vaginal walls Reference to the labors of Bischoff, Martin, Hegar, Kaltenback, Schatz, Emmet and others will show this to be correct After performing colporraphy posterior, Martin makes what may be called an extension of the perineum forward This is an excellent method of restoring the anterior curve of the lower end of the vagina Any surgical procedure, to be successful, must conform to the anatomic structures The denudation of the lateral vaginal sulci or the flap operations conform to anatomic conditions, and so far have proved successful The reason denudation in perineorraphy is so successful is because healing in the vagina occurs with considerable certainty

THE METHODS OF PERFORMING PERINEORRHAPHY

The methods of perineorrhaphy may be classified into three divisions, viz Those which started at the vulva (denudation), those which attack the lower vaginal portions (denudation), those which depend on the flap procedure (which embraces colpoperineorrhaphy)

Numerous methods of perineorrhaphy have been tried since the days of Ambrose Paré, Dieffenbach and Baker Brown, when they simply united the superficial tissue which was situated on each side the visible laceration This was a superficial vulvar procedure and was of small value except to prepare the way for more useful methods

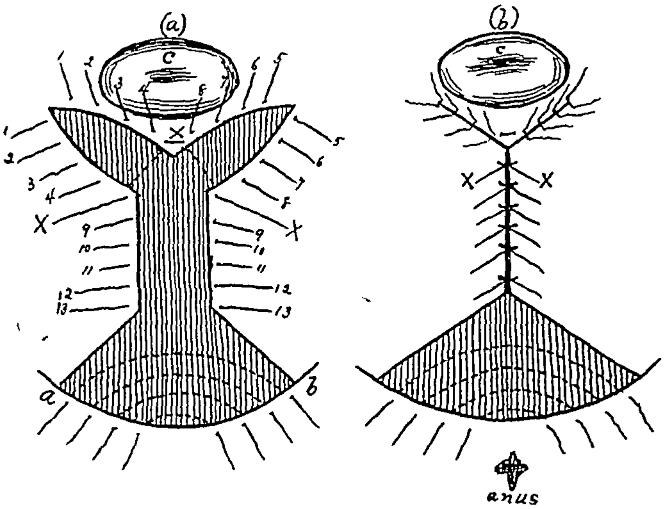

Fig 14, a and b —Dr Reamy's method of colpoperineorrhaphy

HISTORY

If the ancients performed successful perineorrhaphy, I am unable to obtain the records Colpoperineorrhaphy as a modern operation can scarcely boast of being more than a century old Surgeons sought to prevent prolapse by excising of the vaginal wall so that the resulting inflammation would produce a contracting cicatrix Others applied caustics for the same reasons According to Schroeder, Girardin, Laugier employed the blue stone Phillips used "smoking saltpetre," so did Laugier, Velpeau, Kennedy, Dieffenbach, Colles and Simon Chippendale sought to stir up inflammation and cicatricial contraction in the vagina by the very questionable method of infecting it with gonorrheal virus Operators have attacked the vulva or vagina The vulva was first attacked by such surgeons as Baker-Brown and Paré Fricke was the pioneer who performed episiorrhaphy which consisted of denudation of both labia and union by sutures The failures of Fricke's episiorrhaphy induced later surgeons to operate higher up in the vagina, which finally resulted in the Emmet and Tait methods Mende suggested denudation in the region of the hymen Malgaigne thought it should be done deeper in the introitus Jobert cauterized the vagina when it protruded, and after the exfoliation of the eschar, united the raw surfaces with sutures Desgranges employed chlorid of zinc to produce cicatricial contraction Marshall Hall was among the first to employ elytrorrhaphy He cut out oval or long segments of the vaginal mucosa and united the denuded surfaces with sutures Dieffenbach formed flaps Velpeau was one of the first surgeons to do successful perineorrhaphy Langenbeck and Karl Braun were also pioneers in the operation Early operators failed on account of lack of anatomic knowledge and prevailing sepsis It is not many decades since surgeons learned the necessary anatomy to employ in colpoperineorrhaphy It was learned that the perineum must not only be elongated, but a solid, thick, unyielding pelvic floor must be constructed that the sexual organs can not escape Perhaps Simon, the predecessor of Czerny at Heidelberg, was the real founder of colpoperineorrhaphy when, in 1867, he was not only performed but added to it that of posterior colporrhaphy Simon freshened the vaginal wall with a scalpel, and a fenestrated speculum was placed in the vagina while he freshened the upper part of the vaginal wall by having an assistant introduce the finger in the rectum and force the vaginal mucosa out at the vulva Veit, Hegar and Speigelberg aided to develop the operation As time passed, instruments for support were gradually displaced by more perfect operations, owing to more perfect anatomic and pathologic knowledge Most of the advances are due chiefly to the investigations of Freund, Hugier, Martin, Schroeder, Wilms (1879) and Staude (1880), Breisky, Huepfel and others mentioned in this monograph The practical execution of colpoperineorrhaphy by the celebrated Heidelberg surgeon, Simon, is the real foundation of subsequent labors The success attending Simon's addition of colporrhaphy demonstrated that some form of vaginal operation is required in prolapse or deficiency of the peritoneal or sphincter apparatus of the pelvic floor Celsus, it is reported, reorganized perineal lacerations and suggested rest in bed and tying the legs together, but gave no surgical views of repair Ambrose Paré, a fertile genius, demonstrated the use of sutures before 1880 He had a pupil named Guillenneau, who restored the parts, applied the sutures and secured curves Sancerotte and Noel secured success about 100 years ago In 1829, Dieffenbach, surgeon to the Charity Hospital in Berlin, devised useful methods of repair The deductions which made Dieffenbach celebrated in perineorrhaphy were his methods of lateral incisions (to relieve tension) and confining the bowels by the aid of opium Chelius opposed this view, insisting that the bowels should be loose In 1852 Von Langenbeck gave to the world his views through a memoir written by Verhaeghe of Ostend This definitely advocates the use of the flap and splitting of the rectovaginal septum Marcy gives credit to Dr Jenks for originating the flap Zweifel gives Mr Lawson Tait credit for the flap splitting method, to which he is no doubt entitled Hart and Barbour credit A R Simpson with it Baker Brown published in 1854 his first edition of the "Diseases of Woman," in which he advocated Dieffenbach's lateral [illegible]ons, the use of deep quill [illegible] confining [illegible]s with opium, and [illegible]on of th[illegible]

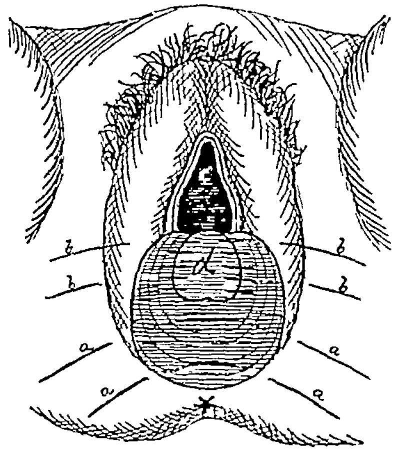

Fig 15 —Colpoperineorrhaphy according to Bischoff The tongue-shaped portion of the posterior wall of the vagina d is not dissected away The denudation in this operation is severe and bleeding is active, and should the operation fail much damage is done a a, and b b, show the method of introducing the sutures and the shape of the denuded area.

The perineal sutures were removed the third day, the remainder later, as late as twelve days All sutures were silk It appears that Dieffenbach and Baker-Brown realized that the denudation should be carried up into the posterior vaginal wall, the fact which Simon actually demonstrated It is reported that Mettauer of Virginia in 1830 used lead sutures, other metallic sutures were also employed In New York, in the Woman's Hospital, Drs Sims, Emmet and Thomas further developed colpoperineorrhaphy

At present the operation should be termed colpoperineorrhaphy New aids have also been developed in regard to the operation, as A Martin taught for years that one should begin the operation for colpoperineorrhaphy by setting up an involution of the uterus by amputating the cervix I have amputated the pointed conical cervix to get rid of the dangerous dilating wedge to the sphincter apparatus of the pelvic floor, to prepare for successful colpoperineorrhaphy A new era appeared in this operation when the flap began to be formed So far as records are accessible, the late Berlin surgeon, von Langenbeck, in 1852, first described the flap operation in perineorrhaphy He describes the splitting of the rectovaginal septum making a vaginal flap forward and a rectal flap backward Langenbeck's description of perineorrhaphy, as translated by Dr Marcy, is the most important contribution to the subject before the time of Simon of Heidelberg In fact, it is almost equivalent to Simon's, and in one sense superior—in the use of the flap Perineorrhaphy was also cultivated by Zary, Mursina, Mensel, Osiander, and Horner Perineorrhaphy was first performed with silk sutures, the hot iron, and chemicals About three-quarters of a century ago metallic (wire) sutures appeared In 1879, Werth published views on the use of catgut (animal ligatures) for buried sutures Schroeder chiefly introduced the buried spiral catgut sutures in perineorrhaphy Silkworm gut is one of the best materials for sutures in general use at present About 1872, Mr Lawson Tait began the use of a certain flap method, consisting of resplitting the old cicatrix by the use of scissors, reuniting the produced wound surfaces by means of sutures which do not penetrate skin or mucous membrane The utility of this consists in its application to either, or both, perineorrhaphy or colpoperineorrhaphy The flap operation was dimly begun by Dieffenbach, in 1829, by his lateral incisions to relieve tension The flap operation was definitely introduced in perineorrhaphy by von Langenbeck, about 1850 ("Memoire," 1852, by Verhaeghe) In 1861, Colles of Dublin, in a case of vesicovaginal fistula, resplit, instead of pared, the edges, and united the resultant flap In 1872, John Duncan resplit the edges of an artificial anus and reunited them with interrupted catgut sutures He forced the flap of mucosa upward and drew the flap composed of musculous and serosa outward, thus increasing vastly the denuded surface for coaptation Hart and Barbor report that Dr A R Simpson applied this flap method to perineorrhaphy Not far from 1872, Mr Lawson Tait applied the flap operation of Langenbeck, Colles and Duncan to the subject of perineorrhaphy He added to all previous labors the use of sharp-pointed elbow scissors, and the introducing of the sutures without penetrating the skin or mucosa of vagina or rectum Silkworm gut sutures are employed and may remain in situ for ten days to six weeks According to Sanger, Stein, a Dane, and Voss, a Norwegian, used similar methods Later, Hadra, 1887, contributed valuable views on the restoration of the pelvic floor as well as Marcy, Jenks, Byford, and Reamy

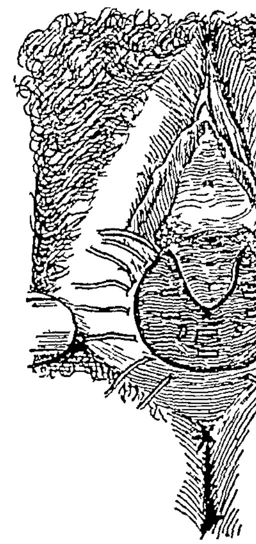

Fig 16—Dr Skene's method The area D, S is denuded, with sutures in situ ready for tying The method resembles that of Hegar and Staude

The various so-called operations for (colpo) perineorrhaphy are numerous The first operation devised involved the vulva, the second both vulva and vagina

1 Ambrose Paré (1580) used simply sutures His pupil Guillenneau practiced and improved the method (1649) LaMotte, Smellie, Noel Murenna and Sancerotte practiced it

2 (1830) Dieffenbach, union by sutures, and tension relieved by lateral incisions Roux (1834) introduced it into France, as well as Mark See (1885), and Palaillon (1885)

3 X Baker-Brown (1885), union by sutures of the denuded surfaces Wilms and Staude cultivated it in Germany

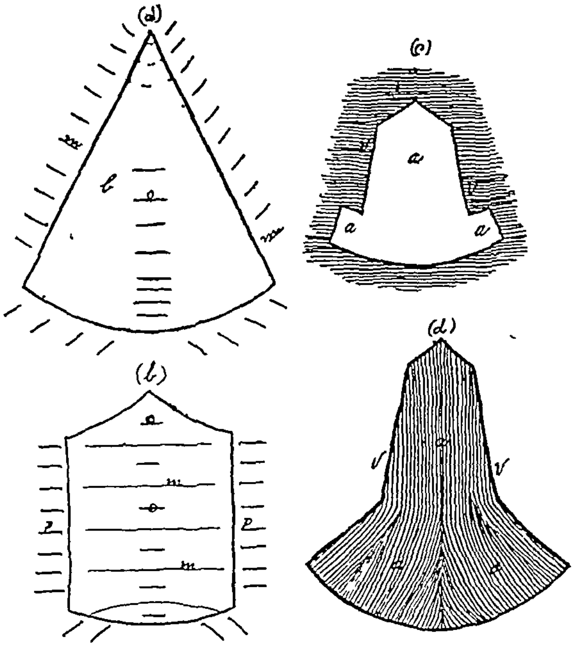

Fig 17—Shapes of the denuded areas in colpoperineorrhaphy a Hegar b Simon c, Lossen d, Fitch In a and b the dotted line represent the sutures buried by tissue the black lines the exposed sutures

4 The next important contribution and method devised in perineorrhaphy was von Langenbeck's flap method (1850) It was described and performed with a master hand Von Langenbeck also suggests that

the lateral incisions of Dieffenbach may be added, as it obviates dragging from movements He advocated removal immediately after the injury, if possible Von Langenbeck makes several distinct steps in the operation vivisection of the free border of the recto-vaginal septum, the undoubling of the septum and the formation of the flap destined to form in the new perineum, the anterior side of the triangular space formed by two canals, vagina and rectum, with the perineum as the base, the vivisection of the two lips of the laceration, the insertion of the sutures In this operation of perineorrhaphy von Langenbeck started the flap method The flap operation protects the wound from secretions (vaginal or rectal)

5 In 1867 Simon of Heidelberg began the real modern steps in successful perineorrhaphy, which was a combination of perineorrhaphy and posterior colporrhaphy Simon simply improved on Baker-Brown's method by not only freshening the perineum, but also carrying the denudation high up into the vagina Simon denuded the vagina by the aid of a fenestrated speculum The upper angle of the vaginal wall was denuded by introducing the finger into the rectum Spiegelberg and Veit aided in developing the subject Englebait wrote in 1871, Banga in 1875 wrote a thesis on "Kolpo-perineorplastik" according to Bischoff In 1879 Hegar and Kaltenbach made excellent contributions In 1877 Le Fort, and Neugebaum in 1881, added their labors In 1877 Dr Edward W Jenks of Detroit began the publication of a series of articles on perineorrhaphy which was really a flap method of operating—a distant relative of von Langenbeck's procedure Dr Jenks first cut away the flap, but afterward preserved it The method is almost precisely similar to the flap method attributed to Dr A B Simpson by Hait and Barbour In 1879 Werth began to use buried catgut to suture the wound Dr Bröse, in 1883, used buried animal ligatures H O Marcy published a series of articles (1883) on perineorrhaphy, advocating the flap method and buried animal ligatures, which he first used in hernia in 1881 A Martin of Berlin contributed excellent labors about 1882 About 1880, Professor Schroeder of Berlin contributed excellent results by the use of the "étage" stitch It was a continuous running suture of catgut buried in the tissues of the denuded surfaces As a pupil of Schroeder and Martin, I observed excellent results from this method Bischoff in part revives the flap operation of Langenbeck However, his operation was quite influential in its day Drs Byford, father and son, made valuable contributions to the subject History notes that Simpson carried Duncan's flap-splitting to the perineum Simpson performed a kind of four-flap perineorrhaphy for many years Perhaps Mr Tait imbibed some of his views

(To be continued)

A LIGATION OF THE EXTERNAL ILIAC ARTERY

BY G G DARLING, M D

ANN ARBOR MICH

The town of S may be considered slow and dull, but it is nevertheless patriotic The Fourth of July was celebrated there, this year, in a truly old-fashioned way, though the only ordnance available was a combination of two anvils and a large wagon-nut The hole in one anvil was filled with powder, and the nut, two inches in diameter and half an inch thick, was placed over the hole, and likewise filled with powder for good measure The second anvil was placed upon the nut to confine the charge The volunteer artillery company did not consider that the addition of the nut to the infernal machine would increase the danger and retreated but a short distance when the fuse was lighted Don L, a lad of seventeen, was standing on the opposite side of the street, some thirty-five feet from the anvil at the time of the explosion Simultaneously with the report he experienced a sensation of having been struck a severe blow immediately above the symphisis pubis There was no pain commensurate with the severity of his injury A few moments later, blood trickling down his leg apprised him of the fact that he had been wounded He walked home, a short distance, and Dr Sheeder was called Dr Sheeder states that in examining the patient he found a wound, nearly round and about an inch in diameter, immediately above the pubes and a little to the left of the median line The deeper tissues fell back into place so that examination with the probe failed to locate the foreign body When the clothing was examined it was found that two thicknesses of cloth had been cut away from the trousers, leaving a hole about one inch by half an inch in dimensions a piece the same size had also been cut from the shirt These pieces of cloth had been driven into the wound by the projectile

Dr Sheeder washed the wound with a bichlorid solution, made a counter-opening to the left of the point of entrance, and put a drainage-tube in these openings The patient suffered but little pain or discomfort He was kept in bed, on a low diet, and the wound was irrigated daily with bichlorid solution On the fifth day the fragment of shirt appeared in the wound and was easily removed At a subsequent dressing fine bits of gravel came away, indicating that the iron struck the ground and rebounded before inflicting the injury By this time there was considerable induration of the tissues in the inguinal region, so that the thigh was flexed and partially fixed The urine was passed with difficulty, but more readily when the patient was sitting upon the edge of the bed On the seventh day, while sitting on the edge of the bed to void urine, there was a sharp arterial hemorrhage from the wound This ceased when the patient resumed his usual position—on his back with the thigh flexed The recurrence of the hemorrhage several times under the same conditions alarmed the patient's friends, and counsel was called I reached S at 10 P M, the seventh day after the injury, saw Dr Sheeder and from him obtained the history as above given I found the patient quite weak from the loss of blood He was lying on his back, the left thigh flexed upon the body, with a pillow passed under the knee for support The left leg was slightly cooler to the touch than the right There was no femoral pulsation on the injured side Before proceeding further with the examination, I requested him to sit upon the edge of the bed as he had done previously when the hemorrhage had occurred He did so, and a sharp hemorrhage followed, which stopped promptly when the horizontal position was taken

The necessary instru [illegible] th [illegible] of tion were prepared, and [illegible]
After enlarging the sk [illegible]

my finger into the opening, and was able to feel a hard foreign substance which lay behind Poupart's ligament and beneath the artery. Its relation to the vein I could not accurately determine. When the tissues were pushed aside, the external iliac artery was easily felt and so far exposed to the touch that I could easily grasp it between my finger in the wound and my thumb outside, if hemorrhage should follow the removal of the foreign body. I then seized it with a pair of forceps and withdrew what proved to be nearly one half of the nut which had been used in firing the anvil. A gush of blood followed its removal, but by thrusting my finger into the wound and grasping the vessel, as I had planned, the bleeding was completely controlled. Under my direction, my assistant, Dr. Burr, cut down to the vessel and secured it with a catgut ligature. A second ligature was passed one-half inch above the first for greater security. Now came the question of ligating the vessel on the distal side of the wound. The clot in the distal portion was already one week old, and the wound was comparatively free from infection, why disturb this natural hemostatic to apply a ligature? Acting on the supposition that a clot which had effectually blocked the artery for a week, must, in the absence of suppuration, be sufficiently organized to continue to do its work, I decided to break a well-established rule of surgery and not ligate below the injured point. The wound was washed and lightly packed with gauze. The opening through which the iliac had been ligated was left to heal by granulation.

Two days later, Dr. Sheeder informed us that another piece of cloth had come away. A week after the operation I went to S. and found the patient doing well in every respect, though the third piece of cloth had not yet appeared. Three days later it presented in the wound, but a vigorous transmitted pulsation warned the doctor that its close connection with the vessel rendered its removal at that time unwise. It subsequently sloughed out without doing any damage, and the wound healed. He does not experience the least discomfort from the change in the course of the blood.

The following features of the case are worthy of note: That fatal hemorrhage did not immediately follow the receipt of the injury, that the iron and the cloth should have effectually blocked the wound in the vessel for a week, that there should have been so little infection or fever, that the formation of a clot made it possible to successfully treat a large wounded vessel by ligature above the wound alone, that in the passage of the iron across the inguinal canal in the upper portion, there should have been no damage to the spermatic cord, and that the external iliac vein should escape serious injury.

SOCIETY PROCEEDINGS

The Chicago Society of Internal Medicine

First Regular Meeting, June 23, 1898.

Dr. John A. Robison, the President, in the chair, and twenty-seven members present.

Dr. Gustav Fütterer read a paper[1] entitled

HOW SOON DO BACTERIA WHICH ENTER THE PORTAL VEIN BECOME DISSEMINATED THROUGHOUT THE SYSTEM, AND WHEN DOES THEIR ELIMINATION COMMENCE?

After showing, from the literature, that bacteria can pass through the walls of the intestinal canal, without grave lesions being present, and enter the general circulation, the writer set for himself the task to inquire experimentally whether, after they had entered the branches of the portal vein, the liver would offer any marked resistance to their reaching the general systemic circulation.

In the several experiments the bacillus prodigiosus and the bacillus pyocyaneus were the germs used, and every precaution was taken to prevent outside and accidental contamination and to render the results conclusive. The bacteria, with physiologic salt solution, were injected into the portal vein of dogs and blood taken from a jugular vein, at varying intervals of time, was used to inoculate culture media. As a result of five experiments the author concludes that micro-organisms may pass from the portal vein into the general circulation within one minute's time.

As to the second question: When does the elimination of bacteria commence? the author states that it begins immediately. He has tied the left ureter of a dog, injected bacillus prodigiosus into one of the jugular veins, taken specimens of urine from the pelvis of the corresponding kidney and found identical germs present within two minutes' time. In another experiment upon a dog, the common bile duct was laid bare and a canula introduced and bile obtained after the bacillus prodigiosus was injected into a jugular vein, with positive results after two minutes' time. This experiment, with extraordinary precautions in the technic, was repeated with like results. From these experiments the author concludes that the elimination of micro-organisms which find their way into the general circulation is inaugurated at once by the kidneys and the liver.

Dr. Billings said that every practitioner has seen clinical evidence of that which has been verified by the praiseworthy and valuable experimental work done by the author.

Dr. Gentles said that when it is considered how long the typhoid bacillus may remain localized in the gall bladder, he could not help feeling astonished at the short time which elapsed between the injection of bacteria into the portal vein and their appearance in the jugular vein, as detailed by the author.

Dr. George F. Butler read a paper[2] entitled

CHRONIC PARENCHYMATOUS NEPHRITIS AND AORTIC REGURGITATION, WITH ENORMOUS DILATATION OF THE HEART.

The case presented was that of a man 65 years of age, who several years ago had acute articular rheumatism and gonorrhea. He dates his present illness to three months ago, complaining of shortness of breath on exertion, cough, palpitation, nausea and vomiting, constipation and great weakness. There are present arterio-sclerosis, visible pulsation of arteries of arms, pulse rapid and collapsing, a blowing systolic murmur at apex which is transmitted to left axilla, an aortic diastolic murmur, a double murmur in the femoral arteries, enlargement of the heart especially on the left side, hepatic enlargement, edema of legs, and albuminous urine with hyaline and granular casts. From these symptoms and findings is based the diagnosis of general arterio-sclerosis, chronic parenchymatous nephritis, aortic regurgitation and hypertrophic dilatation of the left ventricle. The mitral systolic murmur is considered as being due to a mitral incompetency secondary to the ventricular dilatation. After discussing further the diagnosis of cardiac valvular disease and exhibiting sphygmographic tracings taken from this case, the author passed on to the subject of treatment. Digitalis was characterized as the typic cardiac stimulant, indicated in all cases of hyposystole, irrespective of the nature of the valvular lesion, but having its action guarded by a vaso-dilator in cases such as the one detailed. He advises the use of digitalis in efficient doses, with opium in small doses as a vaso-dilator. In the case given, 15 minims of the tincture of digitalis, with 5 minims of the deodorized tincture of opium, was given, every four hours at first, but with gradually increasing intervals, with excellent effect. In addition strychnia, cholagogue cathartics and a careful diet were employed. In conclusion the author made a plea for individualized treatment based upon a broad pathologic conception of the case and a familiarity with the physiologic action of the remedies employed.

Dr. Patton had seen the case with Dr. Butler. At that time doubt was expressed by some of the hospital internes as to the presence of aortic regurgitation, because of the effect upon the pulse tracing by the administration of digitalis. As the paper stated, that, and the great enlargement of the heart, which was much larger than is found in any other condition, was regarded as a strong point in sustaining the diagnosis, aside from the presence of a murmur. The tracing is of interest in this connection because some authors still teach that in aortic regurgitation digitalis is a dangerous drug, to be given, if given at all, with caution This, in the abstract, he had always regarded as fallacious teaching, because we obtain, relatively, the same effect from digitalis in the lesion in question as in any other, only it is necessary to give much larger doses in order to get the same result For instance, in using digitalin, one of the most active of the alkaloids of digitalis, he frequently gave a dose up to ⅓ grain of Merck's product, although the books say the dose is about 1/50 grain and that above 1/30 grain is a dangerous dose In this particular class of cases, with the left ventricle secondarily involved, it is necessary to give large doses Mention was made of the case of a lady of 80 years, with atheromatous stenosis, who is taking, with great benefit, ⅙ grain doses of digitalin, and the sphygmographic tracings exhibit the same beneficial change as in Dr Butler's case

---

[1] Published in full in "Medicine" for July, 1898.

[2] Published in full in the Medical Standard for August, 1898.

Regarding the administration of digitalis the speaker did not suppose that anyone would attempt to obtain its effects in any valvular lesion without appreciating the dynamic force of the circulation, the relative amount of hypertrophy and dilatation and the peripheral resistance to the circulation The reason why the heart fails in dynamic power is, that there is a perivascular sclerosis which interferes with nutrition and the heart muscle becomes degenerated and weakened It dilates and symptoms of a failing heart arise, because the intraventricular pressure exceeds the contractile force of the heart muscle, this can be counteracted by giving something that produces more dynamic force and if digitalis does not do this, he did not know what does The dose must be such that produces sufficient contraction to overcome the resistance If small doses do this, well and good, but in his experience he had found that it will take relatively twice as much digitalis to produce the same amount of contraction of the ventricle in an aortic as in a mitral lesion Failures are often due to disturbance of the normal relation between the peripheral resistance and the contractile force of the heart The peripheral resistance becomes relatively too great and must be reduced by a vasodilator Opium is very serviceable for this purpose, from 3 to 5 drops of the deodorized tincture usually being sufficient Such doses are harmless, even in cases associated with nephritis With the exception of nitrite of sodium, the action of the other vasodilators is too transient Nitrite of sodium is very useful in these cases and the balance of the circulation can often be restored by its use

Dr Goodkind said that he saw, recently, at the Michael Reese hospital, a case similar to that of Dr Butler's With marked symptoms of cardiac insufficiency, due to combined aortic and mitral regurgitation, there were general anasarca, double hydrothorax, renal stasis, etc The patient was given, by mistake, 2 drams of a freshly prepared tincture of digitalis The error was not discovered for an hour, when the stomach was emptied, bringing away some of the digitalis The following was the first good night's rest the man had obtained in months Since then the anasarca has disappeared, the pulse has become more rhythmical, and there has been a very marked improvement in all his symptoms, subjective and objective

Dr Babcock said that while he believes in the use of digitalis in this class of lesions, he differs with the author of the paper and previous speakers with reference to the dosage He can readily understand that in many of these cases large doses of digitalis not only may be well borne, but may be absolutely indispensable to obtain the effects desired This leads him to say with reference to digitalis generally, the dose should be determined by the effects, but on the whole he believes that it should be the smallest which will produce the desired effect That many times we can accomplish excellent results with small doses if the heart is relieved of much of the burden it has to bear It is a mistake to pour in digitalis without lightening the heart's work While he knew that the gentlemen who preceded him realized this fully as well as he did, the general practitioner, who does not see many of these cases might be led into error by reading a statement that cases of aortic regurgitation in general require larger doses of digitalis than others One great danger in these cases is the condition of the arteries secondary to or associated with the cardiac lesion The arteries are sclerotic, and if the left ventricle becomes again powerful in its contractions, and if the vigor of the myocardium has not become greatly impaired, large doses of digitalis might readily cause the heart to throw a volume of blood into the arteries with such force as to cause a rupture of some of the degenerated vessels He believes this is not an imaginary danger Furthermore, if the dilatation of the left ventricle is due to the cause assigned by Dr Butler, viz, the increase in the systole required to overcome the obstacle rather than to the reflex of blood into the ventricle during diastole, then the digitalis in large doses might bring about an increase of dilatation Dr Babcock said he is not convinced that the cause of the dilatation is that assigned by Dr Butler, but if it is, it seems to him that the reason he assigns is an argument against large doses of digitalis In the treatment of these cases he lays particular stress upon sufficient rest in bed and the removal of obstacles to the emptying of the left ventricle by lessening peripheral resistance He also appreciates the wonderful effect of opium in all cardiac cases, but that we must here also speak a word of caution against its general use in connection with digitalis It is in chronic cases that digitalis has to be prescribed for a long time, for months and often for years, and if opium is combined with it, the opium habit is likely to be formed The argument might be advanced that if it prolongs life it is of no consequence, but it seemed to him that if we could accomplish with small doses of iodid of potassium practically the same results, so far as the vascular system is concerned, we should use it because it is better for the patient and it certainly is devoid of many evil effects on digestion which are caused by opium, and the nutrition of the patient is a factor of much moment and one which we must never forget, for it is upon the nutrition of the myocardium that the heart depends

Dr Billings alluded to the differences of opinion as to the diagnosis and treatment, especially as to the use of digitalis, which, almost of necessity, prevailed among clinicians He believes, however, that in that form of insufficiency which is due to real, endocardial, valvular disease, there is great risk to life in the use of an agent which causes violent contractions of the heart In cases due to atheroma and consequent shrinking of the valves there is no possibility, or probability, of washing off any foreign material As to the use of digitalis in these old people with arterial changes, he believes we all differ in our views, as may be seen by reading the journals and text books But he does not think that there is much danger of the rupturing of an artery, because if the heart is so weakened by disease that there is a loss of tension, then there is a lack of arterial pressure, the blood being dammed back on the venous side, as shown by the enlarged liver and spleen and congested kidneys Digitalis fills the arteries and carries the blood forward He agrees with Dr Babcock in that more is to be gained by rest and emptying the right side of the heart than from digitalis Digitalis forces the blood stream and improves the venous circulation, but this may be done in an easier and less dangerous way He quite coincided with Dr Babcock as to the use of digitalis with opium, but thinks opium is contra indicated in cases where the kidneys are involved, with a diminished quantity of urine In cases of uremia absolute physical rest increases the elimination of urea In conclusion, he remarked that the longer he practiced medicine the less digitalis he used, particularly in some valvular lesions, and resorts to smaller doses

Dr Rosenthal considers the state of the pulse the only reliable guide in the use of digitalis The *pulsus celer et altus* will not allow digitalis, as arterial rupture might ensue German authors, generally, teach that there is a difference between the tincture and the infusion of digitalis preferring the latter, and this was also his preference He considers digitalis inapplicable

Dr Wells stated that his remarks would be limited to the question of diagnosis, which was particularly worthy of consideration in this connection because the case presented by Dr Butler was not, from a diagnostic standpoint, a typical one of aortic regurgitation The murmur, to be sure, is present, but this is one of the least important of the diagnostic features of aortic incompetency, in any case it is only confirmatory, not conclusive evidence It may be present or it may not, it may be heard at one time and not at another, but that only makes it the more necessary that repeated consultations be made before the final opinion is given as to the presence or absence of a murmur The matter of sphygmographic tracings had attracted much of his attention for many years, and he believed that in aortic regurgitation the sphygmogram was, in the immense majority of instances, highly suggestive and even distinctive of this lesion The typic tracing (several of which were presented) is one in which the ventricular wave rises to a great height, is very steep and has a sharp apex, a very rapid fall, often to one half or more of the ventricular wave, then there is a sharp upturn, the elastic recoil, which also has a rather sharp apex He had not seen, in his cases, so far as he could recollect, the dicrotic, or peripheral recoil wave absent, and it is always present in typic cases When fever is present the peripheral recoil may be so marked as to show profound dicrotism He could not understand how the Corrigan pulse could be absent in cases of marked aortic regurgitation, with enlargement of the left ventricle, even though the right ventricle be also enlarged The entire question of hypertrophy is an important c [illegible] it [illegible] be remembered that when the left vent[illegible] and forces the blood through the arteries with great velocity and power, the muscular and fibrous tissues in the arterial walls also become hypertrophied, the whole process, cardiac and vascular, going along, hand in hand He believes that the peripheral symptoms, the visible pulsation of arteries that normally do not so pulsate, the capillary pulse in the nails, forehead, gums, tonsils, etc , are of great import, yet he must add a word of caution to laying too much stress upon these without careful consideration of the case as a whole

The **President** cited the case of a lady of 60 years, with aortic insufficiency, who was confined to her bed for two years on account of hemiplegia At the end of that time the cardiac dilation was less, her heart was greatly improved, and the secondary symptoms of the aortic regurgitation had disappeared This case shows what rest alone is capable of doing in these subjects In cardiac valvular disease he had had great success with the old mixture of digitalis, nitrate of potash and cubebs

Dr **Butler**, closing the discussion, said that doctors would differ, although their objects were the same For this reason he would not take issue with those who differed with him in the points brought out in his case His experience justified him in the use of remedies as designated by him Numerous cases of aortic insufficiency had been treated by him in hospital, where the internes had begun with small doses of digitalis, the patients not improving nearly so well as when the doses were increased In one case 10 minims of the tincture of digitalis had been given three times a day for some time without benefit The dose was increased to 15 minims and the intervals lessened and in a short time the man was able to be up and around He quite agreed with Dr Babcock in the undesirability of giving more digitalis than necessary, if 10 minims were efficient it is enough, but if a dram is required give it In regard to the danger of rupture of atheromatous arteries from the use of digitalis, he had never seen a case, and did not think the matter especially worthy of attention He had seen numerous cases of delirium tremens, many of which were old men with sclerosed arteries, who were treated by the hospital steward with tincture of digitalis in large doses, often from 4 to 6 drams, entirely regardless of the condition of the circulation Marked results were always obtained and no one ever killed In short, he had never seen any bad effects from the use of digitalis As regards rest, he quite agreed with Dr Billings that it is a very essential factor and one which was too often slighted He had been interested in the tracings exhibited by Dr Wells, but supposed they were uninfluenced by medicine, whereas his first tracing was without medicine and the others after use of digitalis and opium Personally, he preferred opium as, judging from his own experience, it did not disturb the digestion so much as potassium iodid, and as to its influence upon the kidneys, he paid no attention to that, as he never gave more than 3 or 4 minims of the deodorized tincture of opium He had had patients on this treatment for months and they had not formed the opium habit In cardiac cases with much dropsy he uses diuretin, the theobromin of which causes the diuretic effect, while the salicylate dilates the blood-vessels The combination spoken of by Dr Robison he thought especially useful in cases with ascites and hepatic lesions

Dr **James B Herrick** read a paper

ON THE EXISTENCE OF EPIDEMIC CEREBRO SPINAL MENINGITIS IN CHICAGO, WITH REPORT OF A CASE WITH AUTOPSY [3]

Dr **Fütterer** had seen, a few months ago, in consultation, a case of epidemic cerebro spinal meningitis, in a boy of 12, with recovery

Dr **Hollister** had seen a case, fatal on the twentieth day, which had presented all the essential features of epidemic cerebro spinal meningitis, thoroughly like those seen in severe epidemics of former years

Dr **Butler** had seen, recently, two cases, one with recovery within a month, in which the diagnosis of epidemic cerebro spinal meningitis was positive, and a number of other, hospital, cases in which the diagnosis had been in doubt

Dr **Billings** expressed pleasure in having seen the slides and cultures of the diplococcus intracellularis meningitidis which the author had presented He had been seeing cases of epidemic cerebro spinal meningitis, in small numbers, for several years, and in speaking with colleagues, particularly Dr Church, he believed his experience is but that of others, and that these cases occur, not universally, but in foci, every year in Chicago In his opinion these cases should be isolated

The **President** stated that he had seen three cases of epidemic cerebro spinal meningitis in Chicago during the past few months The diagnosis seemed positive, one dying and two recovering They were all encountered in the same neighborhood

Dr **Herrick**, closing the discussion, said that he was sure there were always sporadic cases in Chicago, and this is the testimony of physicians in almost every large city After epidemics there are always stray cases which creep in here and there Councilman, in a recent article, mentions this and cites the experiences of some of the older New England physicians who went through epidemics and for years saw cases cropping out here and there Sporadic cases, he says, are usually present in many of our large cities Dr Herrick remembered that during the World's Fair there was a little nest of cases out at the Fair, and he attended one case at the Presbyterian Hospital Some twenty or thirty cases were sent to the County Hospital, all from the same neighborhood All the cases which the author referred to in his paper came from a wide area on the West Side—from Lawndale near Twenty ninth Street on the south to Armitage and Milwaukee Avenues on the north With regard to the contagiousness of the disease, he could say nothing from personal experience, but from reading Councilman's article he should judge that it was not ordinarily contagious, and he believes Dr Billings' proposition to isolate these cases is unnecessarily severe In the Boston epidemic of thirty one cases only a few came from the same house, the majority being from separate houses And yet there are those who believe in the contagion of the disease in the ordinary sense of the term It is a disputed point as to how the organism gains entrance into the meninges It probably does so through the nose, as is shown by the investigations of Schiff, who found, in examining nasal secretions, that there is present in the nose, in a large percentage of cases, an organism which is either identical with or, at present, indistinguishable from the micrococcus intracellularis meningitidis of Weichselbaum The experience in epidemics seems to be that the contagious element is a very mild one

Edward F Wells, Secretary

Chicago Medical Society

Regular Meeting Held in the Society Headquarters, Sept 14, 1898

The president, Dr **Arthur Dean Bevan**, in the chair

The subject for discussion was the

MEDICAL EXAMINERS' BILL,

which was opened with a paper by Dr **J W Pettit** of Ottawa He said there was a growing sentiment among the better class of physicians in the State that some more thorough and practical method of regulating the practice of medicine should be attempted This sentiment had found expression for several years in addresses, papers and committee reports presented to the Illinois State Medical Society, favoring legislation more in keeping with present needs and conditions It was not until 1896, however, that any attempt was made to formulate a bill and secure its enactment The Legislative Committee appointed by the State society that year, recognizing the utter futility of securing the enactment of any law which might be opposed by any considerable number of licensed physicians, and further recognizing the unreasonable and unreasoning antipathy of many physicians of the so called schools to each other, sought a union of the schools in this effort The Legislative Committees of the regular, homeopathic and eclectic schools met and agreed to act conjointly Having nothing to guide them as to the wishes of the profession, they conferred with leading men in all the schools and found them unanimously in favor of the creation of a State board of medical examiners, and separating the license from the degree With this for their guide, they had Judge Shope, formerly of the State Supreme Court, formulate a bill embodying these provisions, which for lack of time could not be submitted to the profession before presenting it to the last session of the legislature Being, as it was, a new departure and containing some radical provisions which were not understood, it met with so much opposition within the ranks of the profession that they did not press its passage This was about what was expected, but served the purpose for which the effort was intended, namely, to elicit a discussion of the subject, and in this way determine the wishes of the profession

The work of the joint committee last year was to carefully frame a bill which would meet the requirements of the present time, and be a step in advance of any attempt hitherto made, and yet not so radical as to excite such opposition within the profession as to lead to its certain defeat

While the profession had been found to be almost unanimous in favor of restrictive legislation as a general proposition, a failure to comprehend or recognize the legal principles which must be observed in framing a measure of this, kind had led to some confusion of details as to methods, and herein lies the difficulty of harmonizing the profession upon some specific measure Unless it can be clearly shown that such a law is in the interest of the public, it will not stand the test of a judicial decision, as the Constitution expressly prohibits class legislation Such regulations are under the police power of the State and must be for the protection of the public and not the profession Whatever advantages may accrue to the profession by such a law must be incidental to the public good Physicians would demean themselves and belittle the profession were they to attempt to secure the enactment of a law for their own protection This principle of protection to the public must constantly be kept in view, and any departure from it would nullify any law the profession might succeed in having enacted Medical license laws are only defensible on the theory that they are needed to protect the public health Any attempt to favor physicians as a class, or one class of physicians at the expense of others, has been declared illegal, hence the difficulty in determining who should be excluded from the privileges of practice

---

[3] Published in full in this Journal, July 2, 1898, Vol xxxi p 20

Unfortunately, too often regularly licensed and well educated physicians subsequently become notoriously irregular as to their methods of practice, but are still under the protection of their legally obtained licenses Unless some more practical method is devised than the present cumbersome and inefficient one, the profession might only succeed by the creation of an examining board, in raising the educational standard without elevating the moral tone of the profession

The renewal clause of the proposed law had this in view by restoring to the licensing body once a year that discretionary power which seems to be the only practicable way to reach this class who make the enactment of such a law necessary This provision puts the quack on the offensive instead of, as now, on the defensive, thus placing the burden and expense of a trial on him, instead of, as now, upon the Board of Examiners This difference will operate against the quack as seriously as it now does against the board It will give the board more latitude in the exercise of its discretion as to what is "unprofessional conduct," and this discretion can not be controlled by judicial tribunals This will make it possible to withhold a certificate for those offenses which are regarded as unprofessional from an ethical standpoint, but are not usually so regarded by a court or jury

The serious objection raised against it is that physicians may inadvertently allow their licenses to lapse and thus unwittingly become violators of the law This can easily be remedied by amending the bill, making it incumbent on the Board of Examiners to notify any delinquent that his license has expired, and giving him reasonable time in which to comply with the law The trifling annual tax is certainly too small a matter about which to quibble

The object of this discussion is not only to bring about a better understanding of the Committee Bill which had been sent to the physicians of the State, and make desirable changes, but to stimulate the necessary interest and enthusiasm to secure its enactment All that seems to be necessary to secure the enactment of this or some other measure into a law is, 1, its endorsement by the medical profession, and 2, the weight of political influence on the part of the profession When the profession is united on what it wants the battle is won Without this union of effort for a specific measure, it will be a waste of time and effort to attempt to secure its enactment

Dr Daniel R Brower said that the proposed bill referred to by Dr Pettit would correct the deficiencies of the old one The State Board of Health should restrict its work to sanitary matters During his term of service with the Board of about one year's duration, not one tenth of the time was given to questions of public health, but most of the time was given to the consideration and regulation of medical colleges and the question of medical practice The proposed bill was an excellent one The only objection urged against it was with reference to the clause requiring a yearly license This feature was the only one by which quackery could be suppressed and good work done by the medical colleges of the State

Dr N S Davis Jr , said the regular profession was heartily in sympathy with the general principle of having a licensing board independent of college degree A bill such as the one proposed should not at any time be advocated as in any sense a piece of legislation for the medical profession only It was in no sense whatsoever class legislation, but was purely and simply legislation for the benefit of the public While there were certain sections of the bill that could, in his opinion, be modified advantageously, yet if there was any possibility of the bill not passing because of modifying it, personally he would much prefer to have it passed exactly as it had been presented

Dr Harold N Moyer said the bill as it now stood met with his unqualified approval in every particular He therefore moved that the Chicago Medical Society endorse the proposed Medical Examiners' Bill, and pledge itself individually and collectively to support it when it comes up for passage at the next meeting of the legislature, and that the President of the Society appoint a member from each legislative district to further the resolution This resolution was seconded and unanimously carried

The proposed bill was further discussed by Drs D W Graham, Sanger Brown, A W Baer, H H McAuley, J S Christison, Arthur Dean Bevan, and the discussion closed by Dr Pettit.

SELECTION

The Epilepsy of Napoleon —No life in its singularity better supports my theory that epilepsy is fundamental to genius, than that of Napoleon, as he was surely one of the most complete examples of genius He not only had motoria convulsions, followed by sleep and unconsciousness, excessive violence without cause, so common to genius, but the phenomena rarely noted in psychic epilepsy—momentary mental absences Nor was an hereditary cause lacking It is well known that epilepsy is often inherited through parents addicted to alcohol Napoleon himself confessed to Antommarchi that his father drank, and he died young of a cancerous affection He was talented, intriguing, and lacking, or almost entirely so, in moral sense It was known he was an old friend and follower of Paoli, whom he abandoned at the time of his exile, and thenceforth became a client of the French governors Napoleon's sisters were very immoral, especially Pauline, who was hysteric, it was she who allowed herself to be sculptured nude by Canova Lucien was selfish, avaricious and sensual The mother, however, was a woman of solid character, resolute, intelligent and imperious

Napoleon was short of stature, barely five feet tall, though he measured five feet, six and a quarter inches from finger tip to finger tip, which is considered by the alienist, a mark of degeneration The mesocephalic head, with depressed temples, was not lacking in anomalies, especially the heavy jaw, with the pendant lemuria that is familiar to us all, the salient cheekbones, arched zygomatic bone and scanty beard which one sees in his youthful portraits, before adulation had transformed the expression of his face The upper and lower parts of his body lacked proportion, the legs being too short in comparison to the trunk, the head sunken between the shoulders, and the back slightly curved He had hyperesthesia to such an extent that he had his room heated as late as July He perceived odors when no one else noticed them He suffered from frequent megrims, and had an exaggerated form of what I call meteorologic sensibility, causing him to feel the approaching changes in the weather, from which he suffered, becoming ferocious when it was damp As is frequent with epileptics, he had muscular contractions, especially when under strong emotion In anger the muscles of his calves twitched When he treated of new schemes he was addicted to what are called Jacksonian convulsions, twisting the right arm and raising the right shoulder, with contortions of the lips and grinding of the teeth From his youth he had regular epileptic convulsions At one time at school in Paris he was to have been punished for insubordination, by wearing coarse clothes and by eating on his knees, but he was seized with such a serious attack of convulsions that the punishment had to be spared In the journal of travel to Margonza in 1801 kept by an unknown lady of the court and in Constant's Memoirs, it is stated that on September 10, Napoleon had one of the nervous attacks to which he was becoming subject Josephine called for assistance and after many hours of anxiety it passed over The Emperor forbade its being spoken of Another time Constant saw him in an attack between epilepsy and incubus lying on his elbows in bed shaking and screaming, he was awakened with much difficulty, and pretended to have dreamed that a bear was tearing his chest Talleyrand saw him in a more marked attack, when, in 1805, he went with the

Emperor to Strasburg One afternoon he saw him go into Josephine's room, soon afterward he came rushing out, grabbed Talleyrand by the arm, almost dragging him into a near room, and confusedly asked him to close the door, when he dropped upon the floor as if dead "He trembled and foamed with convulsions, which lasted about a quarter of an hour Soon after, he began talking, then rearranged his clothes, and recommended silence to us, half an hour later he was on his way to Carlsruhe" Like many epileptics, he had a very slow pulse, 48, and later 60 to the minute

Great were his mental absences Wolsley declares a military plan was adopted at Borodino which insured success, and that the victory was lost by the actual mental paralysis of Napoleon At Dresden, as after the battle of Moscow, he lost the fruit of the battle by a sudden mental absence which prevented him from making a decision, at Moscow he did not decide to comply with the request of his generals and order out the reserve to pursue the Russians His mind certainly was not clear when, at Vasarvi, simply because he was affronted at not receiving a reply from Alexander, he decided, almost without preparation, upon a plan of invasion against a solid war like people, protected by the steppes, the cold, and above all by intense patriotism He was entirely lacking in moral sense, as is common with epileptics, which Taine justly says, made him a great leader Thus at Cherasco he said to the Savoyard general with whom he was treating for an armistice "I wanted to demand in the treaty that was being closed, a fine picture of Gérard Dow, which belongs to the king, and is one of the masterpieces, but I could not see how to put a picture in an armistice, and I feared it would seem a strange freak, especially having the fortress of Coni attached to it" It is the language of a brigand making a redemption In his talk with Metternich at Dresden, when the latter remarked that the late war had cost 200,000 lives, Napoleon answered "What are 200,000 men to me?" Napoleon's complete lack of moral feeling was reflected in the phrase, although purely official, of the bulletin issued from the horrible Russian carnage 'The health of the emperor was never better" No Asiatic despot, even in ancient times, could have dictated a sentence more jarring on the mournful scene of death from which it was issued Madam Remusat relates of Napoleon's having said in a conversation with Josephine "I am not like other men, moral and social laws were not made for me" Upon another occasion, in reprimanding the Bishop of Grand, who did not wish to give his oath as it conflicted with one he had already sworn, Napoleon said "*Eh bien monsieur*, your conscience is nothing but stupidity" The evening of the 13th vendemiaire, being present at the arrangements of the insurrection of the sections, he said to Junot "Ah! if the sections would only place me at their head, in two hours I would install them at the Tuileries, and would clear out all the miserable conventioners" Five hours later he headed the conventioners, and had opened fire upon the Parisians These qualities did not develop late, but were manifested at an early age, even in college he was reticent and deceitful His worthy uncle, Corso, prophesied a splendid future for Napoleon, because he was *master of falsehood*, the eulogium which Napoleon reversed upon Metternich

His baseness reached the point that at a public banquet he spilled some oil on the gown of a great lady, of whose honor he wished to rob her, that he might have a pretext to retire with her into the next room One should read his recently published correspondence to see how, aside from the monumental Cæsarean style of his proclamations, he used a coarse, slangy language It is known that many of the worst letters have been suppressed and will never be seen How unfortunate that he should have shown these qualities even in treating with sovereign and foreign ministers of state, insulting them in his proclamations, his letters and his audiences, revealing their love intrigues, whether actual or supposed The bulletins 17, 18 and 19 after the battle of Jena, openly accuse the Queen of Prussia with an intrigue with Alexander of Russia His unlimited selfishness was shown in Egypt and in Russia when, at a time when everything depended upon him he abandoned the army for the sake of saving himself He would never have raised his brothers and brothers in law and many of his generals, except to have them as instruments in his hand, as reflectors and magnifiers of his own light He thrust them cruelly against their people for his own interests When he crossed into Italy the first time, he began with the phrase "my soldiers" and "my army," and finished by talking of "my people," "my senate," and even of "my bishops," and "my cardinals," as though they were his puppets For arranging, directing and mastering the practical affairs of life, such incomparable and lively passions form a tremendous force

This force was Napoleon's selfishness, not the inactivity of the many, but active, aggressive selfishness, developed to the point of creating an infinite *Ego*, so that in the vast domain in which it acts it can not suffer another existence, unless it be an appendage or an instrument of its own As a child this charateristic existed in him in embryo He was rebellious at every reproof, without scruples, without conscience, intolerant to rivals, ready to fight any one who would not give way to him, while he accused others of attacking him He considered the world as a magnificent banquet open to all, where to be well filled it is necessary to have long arms and help one's self first, letting others have only what is left Man, according to him, is dominated with his same selfish passions of fear, cupidity, self love and emulation Napoleon never departed from these ideas, nor could he, they being a part of his character, he saw man as he choose to see him His selfishness, reflected in ambition, took such possession of him as to kill his conscience, and ambition finally caused his downfall It was not enough that his functionaries were active and zealous, after having killed every critical sense in the man, he must belong to him body and soul, and in the slightest observance he suspected a conspiracy or an attempt upon his majesty He demanded every agreement of service from his functionaries—even though criminal – from the falsification of the Austrian and Russian notes in 1809 and 1812 to the projection of an infernal machine against the Bourbons, in 1814 Gratitude was unknown to him, when a human instrument no longer served him he cast it away Peace for him was an armistice during which he prepared for a new campaign It was for this reason that *all* Europe, taught by experience, united after 1809 in turning against him Napoleon, instead of considering his own personality secondary to the State, considered the State secondary to his personality He had no regard for the future and sacrificed it to the present "If my successor is an imbecile, so much the worse for him" He made the press a slave to Censorship, and even prohibited works of statistics and economy, if they appeared to cast doubt upon his infallibility It was the same with the schools He wrote to his councillors of State "In establishing a corps of instruction my aim is to have a means of directing public opinion in politics and morals" As Renan said, school was for him the vestibule of the academy G Gorion was sent to prison for having called his coronation with the iron crown an absurdity, and Lattanzio was committed to the insane asylum for saying *Napoleon would make himself king of Italy* His brother Joseph said Bonaparte would have had no peace if he could have supposed that after his death everything would go on quietly and smoothly He forced France into an abyss, conscious that he was deceiving her, by misdeeds and an abuse of confidence *there grew by degrees the divorce between his own interests*, such as he understood them, and the public interest Napoleon ended by becoming the slave of his monstrous conceptions and his limitless ambitions Even though the expedition into Russia had not ended disastrously, some other misfortune would have overtaken him In order to carry out such an enormous campaign it would have been necessary to have a tremendous combination of forces The fate of Napoleon's subjects was reduced to a military career or obligatory administration In 1810 there were 160,000 men who refused to serve, and in 1811 and 1812 60,000 were arrested Meantime he had made 4,000,000 victims, France was reduced by two foreign invasions, made a suspect of Europe, surrounded by menaces of odium and envy This was the political work of Napoleon, the outcome of selfishness supported by genius With his false image of glory he promoted what may be called the military and bureaucratic degeneration of France, the worst calamity that can overtake a civilized nation In all this he showed an impulsiveness and above all a brutality common to epileptics As Bonfardini says, he mistook brusqueness for dignity, his own caprice for moral law, anger for justice and insolence for truth It is told that he kicked Volney when he said that France wanted the Bourbons, and gave Bertier a cuff when he saluted him inoportunely, as "Roi de France" While the treaties of peace were being made with the Count Cobentzel, Napoleon suddenly broke a valuable vase, saying, 'I will break your monarchy in pieces like that" At Boulogne, when the admiral refused to collect the fleet on account of a menacing storm, *Napoleon raised his lash upon him*, which he had already used several times on some of the grooms He writes to Prince Eugene, "You will await orders from H M were it only to change the ceiling of your room, and if Milan were on fire you should await orders, although *the whole city burn while you are waiting*" He once violently thrust his brother Louis out of the door In Dresden, in 1813, he brutally asked of Metternich, at a time when he was indispensable to him, how much England had paid him to represent her interests as he was doing Intolerant of delays, he would throw clothes into the fire if he did not easily succeed in putting them on He scrawled, he did not write He dictated with unusual rapidity, and if asked to repeat would fly into a passion, which his secretaries sometime provoked for a rest From childhood he was violent and impulsive He boasted to Antommarchi that as a child he feared no one, struck and scratched everybody, especially his brother Joseph, whom he would bite and kick until interfered with

A leader of high talent, between the alternatives of the throne and the gibbet, he made a game of peoples, religions, and government, with incomparable skill and brutality His gigantic intellect was abnormal for his size Marbot, a reliable authority, attests that he had marvelous nervous force, and had resistance for a work seemingly incredible He could spend ten or twelve hours on horseback, with barely four or six hours interrupted sleep, being wakened for his signatures, only to fall immediately to sleep again, and this upon the eve of battle which would keep him in the saddle all day At Paris, after a day of intense work, he could rise in the middle of the night, dictate to many secretaries, who changed with the precision of sentinels, and in this way go from a conference with his ministers to an audience with literati or artists "The quantity of facts," wrote Taine' "which his mind stored up and retained, the number of ideas which he produced and elaborated, seemed to surpass human capacity, and always as one of experience, of a practicality which contrasted with the abstractions and theories of his Latin education"

"I think more rapidly than any other man" said Napoleon In the art of mastering men his genius was superhuman All his sayings are fire flashes "Liberty," he exclaimed, "is the necessity of a small and privileged class, endowed with higher faculties than those of the mass of mankind, therefore you can lessen or infringe upon it with impunity Equality, on the other hand, allures the rabble" He possessed a faculty which carries us back to the Middle Ages, an astounding constructive imagination What he accomplished is surprising, but he undertook far more, and dreamed much more even than that However vigorous his practical faculties may have been, his poetic faculty was still stronger, it was even greater than it should have been in a statesman, greatness was exaggerated into immensity, immensity growing into madness He was great, yes, but his greatness became a monstrosity What aspiring, gigantic conceptions revolved, accumulated, superseded each other, in that marvelous brain "Europe" he said, "is but a mole hill Only in the Orient, where six hundred millions of men live, can one establish great empires, excite great revolutions" In Egypt he dreamed of conquering Syria, of re establishing the Eastern Empire, returning to Paris by Adrianople and Vienna The Orient allured him with the mirage of omnipotence and in the Orient, he, the new Mahomet, caught a glimpse of the possibility of creating a new religion, while in Europe he dreamed of rebuilding the Empire of Charlemagne, of making Paris the physical, intellectual and religious capital of Europe, assembling within its precincts the princes, kings, and popes who should have become his vassals, then extending his domain through Russia to the Ganges and the Indian supremacy

From the turmoil of politics rose the artist, creating the impossible in the field of the ideal One soon recognizes him for what he is, a posthumous brother of Dante and Michelangelo though they worked on paper and with marble, he worked upon the sensitive, suffering flesh of living man Neither in the Malatestas nor the Borgias does one find such an impulsive brain, in which the internal tempest is so continuous, so menacing, so sudden in its flashes, capable of such electrical changes and discharges, and so irresistible in its shocks In him no idea remained in a mere state of speculation, each was equivalent to an inward convulsion, which immediately extended into an act" This wonderfully reproduces the epileptic mind in its greatest hypertrophy

Although he traveled through Europe so much he never had a clear idea of the social conditions of the people He thought that in a hundred years Europe would be Russian or republican He was blind to the facts of social life His was an intense intellect, with rays of light in various directions, rather than a solar intelligence which sheds light upon all, he felt the truth in an attack of clearness, or he understood nothing There were many old contradictions in his politics, as when he re established the catholic religion and seized the pope He forbids Gérardin to appear at court, because he is divorced, and later Napoleon is himself divorced He declares the glory of his race to have risen at the battle of Marengo, and then affects regal pomp and heraldry One of his oddest caprices was his passion for making marriages, the number he made and imposed was extraordinary When convalescent at Valencia he married the daughter of his attendant to a young acquaintance He married his brothers, his sisters, his nephews, almost all his generals, When some one refused one of his sisters, he offered her to another, and obliged the marriage to be consummated in two days At St Helena he continued to make marriages among his attendants, and among the children of the generals and governors of his suite Even in his will, in a codicil, he asked the Duke of Istria to marry the daughter of Duroc He believed that a star guided him, and at St Helena he showed fear of a comet He was superstitious about Friday When he broke the glass of the picture of Josephine, which he always carried with him, he feared for her life In making war he always selected propituous days He had the rudimental form of doubting insanity, and was not able to go through a street, even at the head of an army, without counting the windows in pairs There is in this great man the combination of genius with convulsive and psychic epilepsy, which is manifested by impulsiveness, mental absences, cynicism, excessive selfisness, and megalomania And by this example, which can not be an isolated case in nature, one can believe it possible that epilepsy is the substratum of genius

If we further analyze the phenomenon of genius under the light of the new theories upon epilepsy which are being solved today by the clinics and experimentalists, we see the justice of the conclusion that genius is a form of psychic degeneration, of the species epileptoid The lesser number of women of genius supports this theory, as women are more rarely degenerate and more rarely have psychic epilepsy It is proved by the frequent anomalies of asymmetry of the cranium, moral insanity, which I have demonstrated in "Criminal Man" as being a variation of epilepsy, hallucinations, intellectual and venereal precocity, somnambulism, double personality, which has two and sometimes three opposing natures, sometimes obtuse, sometimes exaggerated sensitiveness, the anomalies of the field of view, bluntness of perception, the frequency of suicide, which is very common in epilepsy, and above all, amnesia and analgesia It is also demonstrated by a roving tendency and strange fears by which one is seized, misonism, and an affinity to criminality, the point of union of which is moral insanity Add to it the origin and descent from criminals, inebriates, or from imbeciles, which often marks both the genius and the epileptic, and which is seen in the families of the Cæsars and of Charles V It is shown by insensibility and a lack of moral perception which is common in geniuses One might doubt the conclusion who does not know the extent of the field of epilepsy in modern times, since intermittent hemicrania, scialorrhea and amnesia are now recognized as epilepsy Many forms of monomania are but a guise of the disease, at the appearance of which all other pre existent traces of epilepsy often disappear It is enough to mention the number of geniuses of the first order who were taken with motoria epilepsy, vertigo or passionate anger, in which they lost themselves absolutely, besides Napoleon there were Molière, Julius Cæsar, Musset, Petrarch, Peter the Great, Mahomet, Handel, Swift, Richelieu, Charles V, Flaubert, Dostoyewski, Guerazzi and St Paul Those who suffered from vertigo were Dickens, Swift, Herschell, Faraday and Marlborough Vertigo is simply cortical epileptoid which is accompanied by loss of memory or paralysis, as in Dickens and Faraday, and by convulsions, as in Marlborough As to passionate anger, we recall Peter the Great, the parricide, and Byron, who from childhood fell into such paroxysms that it was sometimes feared he would die of suffocation

For one who understands the binominal law, according to which no phenomenon is isolated, but always the expression of a series of less marked though analogous facts, such frequency of epileptic phenomena among the greatest men indicates that it is more extended among geniuses than one would at first think, and that the nature of genius itself must be epileptic It is important to note how seldom in their lives they have convulsions, and that in such cases the psychic equivalent (which creates genius) is more intense and frequent Above all, the identity of the two great phenomena is proved in the analogy between the epileptic attack and the moment of inspiration, the unconscious and violent activity which creates in the latter, acts motorially in the former Most convincing of all is the analyzation of the creative inspiration, which is sudden, intermittent, frequently associated with unconsciousness irregularity of the pulse and often somnambulism and not seldom accompanied by convulsive movements of the limbs or followed by amnesia It is often occasioned by conditions which provoke or increase cerebral hyperemia, and is followed by hallucinations

The close connection between inspiration and the epileptic attack is pointed out more directly in the words of a great statesman, Beaconsfield 'It often comes into my mind that there is but a step between intense mental concentration and insanity, I can not easily describe what I feel in that instant, it then seems to me that my senses wander and that I am no longer sure of my existence. I recall often having been obliged to refer to a book to see my own name written to assure myself that I lived. During this state my sensations are incredibly acute and intense. Every object appears animated, and it seems to me that I am conscious of the rapid movement of the earth." A modern novelist says: "*It is a* fatality that dictates the idea, an unknown force, a supernatural will, a sort of *necessity* to write which directs the pen and in such a way that when the book is written it no longer seems yours, and you wonder how such a thing could have existed in you and of which you had no consciousness, such is the feeling I had in creating 'La Sœur Philomine.'" (Journal de Goncourt.) Zola, too, in the "Roman Naturaliste," gives us this point on the inspiration of Balzac: "He worked under the operation of certain impulses which are a mystery to us; he was the victim of a capricious power. At times for all the gold in the world he could not have written a line, at other times, in the evening, in the middle of the street or in a morning orgie, a burning coal kindled his brain, his hands, his tongue; on a sudden a word awakens hidden ideas which lie fermenting. So is the artist an humble instrument of a despotic power." "My passions," says Burns, "are wild as demons if they do not find a vent in verse." After writing he felt relieved and consoled.

Such are the confessions of Mahomet, St. Paul and Dostoyewsky. In "Besi" he writes: "Suddenly something opened before him, an extraordinary internal light illumined his mind; there are moments which do not last more than five or six seconds, in which you suddenly feel the presence of eternal harmony. This phenomenon is not terrestrial, nor celestial, but something that man in his earthly development can scarcely endure; he would be obliged to transform himself physically or die. It is an ineffable feeling. Suddenly it seems as if you were put in touch with all nature. There is neither tenderness nor joy; there is no forgiveness, because there is nothing to forgive; there is not even love! Oh! it is a feeling higher than love. The joy which fills one is terrible; if this state should last more than five seconds the spirit could not resist; it would have to vanish. During these five seconds I live an entire human existence, and for it I would give my whole life, and should not feel I were paying too dearly." "Are you not epileptic?" "No." "You will become so. I have heard it said that one begins in just that way. A man subject to this disease [evidently it is Dostoyewsky himself] has described minutely the sensation which precedes the attack, and listening to your description it seemed as if he were speaking. He also said that it would be impossible to sustain this state more than five seconds. Do you remember the vase of Mahomet? While it was being filled the prophet flew to paradise. The vase is your five seconds, and paradise is your harmony; Mahomet was epileptic." ("Besi," Vol. i.) And in the "Idiot": "I remember, among other things, a phenomenon which preceded his attacks of epilepsy, the weakness, the mental marasmus, which proved the disease. There were moments in which his brain suddenly became inflamed, and his vital forces all at once rose to a prodigious degree of intensity. The sensation of life, of conscious existence was increased tenfold in these swift moments. A wonderful light burned in his mind and heart. All agitation became calm, all doubts, all perplexities, melted into a vast harmony. But these radiant moments were but the prelude to the last second which was immediately followed by the attack. This second was truly ineffable. When, later, the prince having recovered, reflected upon it, he said himself: 'If these fugitive moments are owing to sickness and the suspension of normal conditions, then they are not of a higher life, but, on the contrary, one of a lower grade. What matters it if it be a sickness or an abnormal tension, when in looking back, recalling and analyzing it, the greatest degree of harmony and beauty are included'?" In this moment did he not have visions analogous to fantastic dreams produced by intoxication with hasheesh, opium, or wine? He could easily judge all these things when the attack ceased. These moments are marked by the extraordinary exaggeration of the inner sense in the last moment of consciousness which precedes the attack the sufferer can say with full consciousness of his words, "For this moment one would give a lifetime." And without doubt the epileptic in this instant understands the allusion of Mahomet when he said that he visited all the mosques in less time than it took to empty his vase.

That we may see how perfect the correspondence is, compare this description of the psycho epileptic attack with the inspiration of genius, as authors describe it. Berlioz says: "A voice comes from my palpitating chest; it seems as though my heart, under the irritation of an irresistible force, expands as to be dissolved by expansion. Then the skin of my whole body aches and burns, I flush from head to foot. I wish to scream, call the assistance of some one who would console and guide me, and prevent my being destroyed, and detain the life which is ebbing away. I have no thought of death during this crisis, and the thought of suicide is unbearable, I wish to live, live with energies a thousand fold redoubled; it is a prodigious *attitude of happiness and a mania for activity, which can not* be quelled except with devouring, furious realization, according to the measure of its intensity." Goethe said that the melody of his verse, like a tiny, independent, impalpable thing, agitated within him before the words were formed, or the thought itself took shape. And Beethoven said, "I have told it, but they did not understand me, as they can not understand the power of artistic inspiration, as they do not understand that I act in accordance with internal laws, unknown to the vulgar, and that I cease to understand myself when the hour of enthusiasm is passed. Fools! In their cold exaltation, in their free hours, they select a theme, they develop, enlarge it, taking care to repeat it in another tone; they add by rule, wind instruments, or some strange combination. All that is very reasonable, very polished, well studied; but could I work so? They compare me to Michel Angelo. Very well; how did the author of Moses work? With fire and furor; in a frenzy, he then made great strokes in the immovable marble, and forced it in spite of itself, to unlock his living thought sepulchered in the block; and I too compose thus. For me inspiration is that mysterious state in which the entire world seems to form a vast harmony, when every feeling, every thought, echoes in me, when all the forces of nature become my instruments, when a shuddering shakes my whole frame, when my hair stands on end." These expressions demonstrate that where genius shows itself in the highest form, and where there is the greatest differentiation from the normal man, in the moment of inspiration he is more or less in that state of unconsciousness which, according to many, is the true character of epilepsy.

"One of the characteristics of genius," writes Hagen, "is *the irresistible impulse of the act.*" And thus is explained by Kant, Coleridge, Voltaire and Cardano, how works of genius can be created in sleep, as this is also a state of perfect unconsciousness, and how the double personality of genius, in the state of inspiration and in the state of normal mind, is a mystery to itself. The most salient characteristic of genius is therefore unconscious creation, which is the most singular, if not the sole phenomenon of epilepsy; and from that, to deduct that it is a specially divine variation of that *morbo sacro* (I do not repeat this synonym without reason) is a step which, even to the least learned in psychic materia, is not difficult. For those who do not know that in many cases the entire attack consists only in a violent excitation of a single sense followed by amnesia, I mention a patient of mine who is seized by a motorial attack, now only by vertigo accompanied by the sight of a bright yellow light, and another whose attack preceded by aura, consisted in atrocious crural and brachial neuralgia, followed by amnesia. I will add that in some not only the attack, but the whole life, records the psychic phenomenology of the epileptic; but over and above all the example adopted here of Napoleon is enough.—Lombroso: *Rivista d'Italia*, March 15, 1898; translated by A. Goodwin Culver, exclusively for the JOURNAL.

PRACTICAL NOTES

The Diazo Reaction in the Urine.—A. Krokiewicz concludes from a study of 1105 cases (16,167 tests) that the Ehrlich diazo reaction is one of the most important means in our possession for the diagnosis and prognosis of phthisis and abdominal typhus, and also of primary carcinoma of the ovaries. The results are more or less negative in all other affections, including the renal. It always indicates an acute course of the morbid process or an impending relapse, and is independent of the number of bacilli in the sputa. It can be relied upon in every case of abdominal typhus, and in miliary and nearly every other manifestation of tuberculosis.—*Vienna Klin. Woch.*, July 21.

Electric Shock.—This must be treated as promptly as possible, and not only with artificial respiration, but with faradization of the respiratory nerves, the phrenicus, vagus and spinal nerves.—*Munich Med. Woch.*, July 19.

ANOMALIES OF THE DUCT OF MULLER AS THE CAUSE OF ECTOPIC PREGNANCY

Rare forms of ectopic pregnancy are those that develop in accessory tubes or in diverticula of the tube Of each of these varieties HENROTIN and HERZOG[1] have recently described an instance

At the fimbriated end of the Fallopian tube may be found certain accessory organs, which are somewhat difficult to describe Some of them, however, are known under the name of accessory tubes They consist of a canal with an open free end surrounded by fringes, the other end sometimes opening into the Fallopian tube proper These structures are congenital malformations, resulting from anomalies of the duct of Müller It must be mentioned, however, that certain authors believe that these structures and orifices may result from inflammatory processes, followed by proliferation of the wall of the oviduct, with hernia of the mucosa The histologic study of such accessory organs in serial sections has shown conclusively that they depend upon an early embryonal anomaly

RICHARD[2] found accessory organs in five cases out of thirty, VALENTINE and WILLIAMS[2] two in sixty-one In the cases observed by KOSSMANN[2] the accessory canal did not have any connection with the oviduct proper, and he therefore believes that these accessory organs result from infundibuliform invaginations of the serous endothelium, and that sometimes such prolongations may connect with the salpinx

HENROTIN and HERZOG then report a case of ectopic pregnancy which developed in an accessory tube This was a small organ which communicated directly with the lumen of the oviduct proper, without any interruption or modification in the mucous lining, which consisted of cylindrical cells in single layer, and, according to their statement, they have been unable to find any example of tubal pregnancy in an accessory tube whose canal did not communicate with the duct proper The instance occurred in a 27-year-old American woman, whose clinical history did not present any peculiar features, the diagnosis of ruptured extrauterine pregnancy was readily made, prompt recovery followed removal of the adnexa and curettage of the uterus

Diverticula of the walls of the Fallopian tube have long been regarded as playing some rôle in the etiology of ectopic pregnancy, but the number of illustrative cases is so far very small One of the most complete studies of the tubal diverticula is that by WILLIAMS,[3] who describes these diverticula as developing in the interior of the tube and as extending up to the serous covering, they may be lined by a single layer of cylindrical cells with cilia, presenting therefore all the characteristics of the mucous membrane of the Fallopian tube proper These diverticula can not be confounded with accessory tubes, because they do not open upon the exterior and can not be readily recognized from the external surface of the tube In his articles concerning tubal pregnancy ABEL[2] calls attention to the fact that a very tortuous tube may in microscopic sections appear as though its canal is doubled or thrown into diverticula The only example of ectopic pregnancy in a congenital diverticulum of this kind is described by LANDOIS and RHEINSTEIN They found an embryo situated in the superior wall of the tube, separated from the cavity of the tube by a band of connective tissue, so that the only explanation of the condition would be the lodgment of the fecundated ovum in a congenital diverticulum

HENROTIN and HERZOG believe that diverticula of the tube of this kind are due to anomalies of the duct of Müller, which has given origin to a secondary branch This division may result in a double opening into the uterine cavity The first instance of this sort was described by BAUDELOCQUE in 1825 The case described by our authors occurred in a patient of twenty-nine The diagnosis of extra-uterine pregnancy was made clinically, and the uterus and its adnexa were removed As the result of the careful microscopic examination of the specimen it was concluded that the ectopic pregnancy developed in a congenital diverticulum which terminated in a cul-de sac, because there was found in this diverticulum the characteristic elements of the decidua On account of its size it was believed that this diverticulum resulted from a congenital anomaly and not from a pathologic process

[2] Quoted by Henrotin and Herzog

[3] American Journal of Medical Sciences 1891 cxxviii p 257

We have abstracted this report because it very clearly emphasized the important rôle that congenital anatomic anomalies may play in the production of pathologic conditions of great significance to the patient

THE RESPONSIBILITIES OF THE ARMY MEDICAL DEPARTMENT

In the JOURNAL of August 13, under the title "An Arraignment of the Army Medical Department," we discussed some of the criticisms of the work of Army medical officers elicited by their reported inability to provide for the comfort and surgical treatment of the wounded after the attack on the Spanish lines at Santiago, Cuba Since then the newspapers have been filled with harrowing reports of suffering in the camps and hospitals, much of which has been attributed to the carelessness, incompetency and inhumanity of the medical men serving with our troops From time to time the Surgeon-General has given to the press extracts from the reports of officers in active service with various commands, to correct the impressions made by the extravagant headlines and sensational exaggerations of certain of these newspapers He has also given statements of the provision made for the sick on special occasions, when the charge had been preferred that the Government had made no such provision But notwithstanding this, so much odium has been thrown upon his department, and particularly on himself, that he has lately given to the papers a definition of the duties and responsibilities of his office "It would require," he says, "superhuman power to meet the expectation of many of those who have criticised the Surgeon-General for his administration of the affairs of the Medical Department of the Army" He apparently has been held to a responsibility for the care of every individual sick, for he explains that regimental medical officers and medical men in charge of wards in hospitals were assigned to this duty He has also been held responsible for the sanitary condition of camps, for he explains that brigade surgeons were appointed to look after the sanitary conditions of brigades, division and corps surgeons to superintend the medical department of their commands, the sanitation of their camps and the equipment and efficiency of their field hospitals, and a Chief Surgeon of the armies in the field to exercise general supervision over the whole It has been urged that the Surgeon-General is responsible for the deeds or misdeeds of his subordinates This would have held good had opportunity been afforded him to test the qualifications of the men appointed to positions in the medical department of the Volunteer Army, but these positions were filled by the State authorities and the appointees very generally had little practical experience in military methods, and particularly in military sanitation As a result of this want of experience, regimental, brigade, division and corps surgeons, however competent as medical men and even as sanitarians in civil life, found it extremely difficult, and in most cases impossible, to control the insanitary influences that pervaded the large camps of hastily organized troops, whose line officers were more concerned with the military equipment and drill of their men than with their preservation from these influences The Regulations of the Army and orders from the War Department published at the suggestion of the Surgeon General give directions with reference to camp sanitation and the care of the sick, and it is the duty of military commanders to see that these are carried into effect, yet the Surgeon General has been held responsible for all the faulty conditions that have been developed by failure to carry out these instructions

The duties of the Surgeon-General are specifically defined, as are those of the regimental surgeon As stated, he makes the assignments of officers as chief surgeons of corps and divisions He has charge of all general hospitals and of hospital corps, of the medical supply depots, of the payment of all bills against the Medical Department, and of the collection of all reports and papers relating to the disabilities of individual men in the military service The general hospitals are those at Key West, Fla , Fort Thomas, Ky , the Leiter and Sternberg Hospitals in Chickamauga Park, the hospitals at Fort McPherson, Ga , Fort Myer and Fortress Monroe, Va , the temporary hospital at Montauk Point, Long Island, and the Josiah Simpson Hospital, a newly finished pavilion hospital of 1000 beds near Hampton, Va The hospital ships are the *Relief* and the *Missouri* The failure of Congress to provide a hospital corps for the large volunteer army which was so suddenly brought into existence, had to be met in part by hastily organizing a force of contract nurses Although the Surgeon-General is responsible for the purchase and issue of medical supplies, it is impossible for him to foresee the local wants in different parts of the country Hence the necessity for requisitions from the local officers The difficulty of getting war material to crowded camps has added a medical phrase to the vocabulary of the newspaper reporter, "the congestion of the lines of transportation" This congestion has frequently been the cause of complaint of want of supplies

It is very evident to one who looks on from the outside, that the difficulties encountered by the Army Medical Department were due to the impossibility of having, in so short a time, an experienced and well-disciplined medical force sufficiently strong in numbers to control the sanitary situation in an aggregation of a quarter of a million of men hurriedly thrown together in military camps Detailed reports from Santiago show how nobly the medical men of the

Fifth Army Corps acted during and after the fight, notwithstanding the failure of the Quartermaster's Department to land and bring up the supplies, yet the press despatches charged them at the time with carelessness and incompetence. Similar detailed reports, when brought out later, will show as clearly the earnest efforts of the Medical Department, from the Surgeon-General down, to protect the troops in the camps in this country from the effects of their own ignorance and want of military training.

INSANE ARTISTS

The recent paretic dementia of MUNKACZI, the Hungarian artist, has attracted no little attention to the question of insanity in artists. Prominent among the many contributions to the subject is ARREAT'S "Pathology of Artists." In this a large number of artists are described as having either acquired or inherited psychoses. What disappears first in insanity is, as ARREAT remarks, the power of special inhibition and general control. The mind is free to impulses born of disease. The artist loses judgment of images relative to his art which are then offered to him. Disorder begins in his ideas of painting and is shown in his choice of subjects and defects of harmony in composition. Errors in design come first, technical memory long survives, that is, the mechanical association of visual and motor images. Though the professional memory of an artist be a thing acquired and improved, yet it has roots in the association of images composed of innate tendencies formed in specially gifted brains.

Sense of color and its contrasts were deficient in early races. Even as high a race as the Greeks exhibited decided deficiencies in this particular. Primeval and medieval art exhibits the same peculiarity and it atavistically appears in the insane. In alcoholic insanity and paretic dementia the color sense is often destroyed. LOMBROSO finds that the alcoholic lunatics use yellow excessively in their pictures. One paroxysmally alcoholic lunatic, who lost all sense of color, became very skilful in depicting white, and between his attacks was the best snow painter in France. A paretic dement artist, after the onset of his disease, collected miserable oleographs which he colored green. (*Alienist and Neurologist*, Vol. xiii.) A paranoiac, at one time under KIERNAN'S care, painted "A Struggle of the Youth and the Amazons" at its voluptuous termination in various tints of green. The effect, which was ghastly in the extreme, recalled the preference of MURGER for women with green lips. The artist was not color-blind, but attached a peculiar symbolism to this use of green. This was clearly a reversion to a fetichistic canon of art such as regulated the productions of the Egyptians and Greeks and appeared in the middle ages as a consequence of the intellectual storm and stress resultant on Christian reaction against fanatic vandalism. The tendencies to undue use of analogies lead to color and shade otherwise inexplicable. Such uses of color lead to interpretations seemingly at variance with the subject depicted. Thus, as RUSKIN has pointed out, some of CORREGGIO'S Madonnas—and the same is sometimes true of RAPHAEL—often suggest voluptuousness. On the other hand, Phryne has been so depicted as to create sympathy for violated purity. Many of these contrasts pushed to the extreme appear to be insane, from the tendency to attach occult significance to trivial analogies. In "His Masterpiece" ZOLA vividly depicts this innate insane tendency to symbolism which causes terrible defects to appear in the otherwise beautiful paintings of Claude Lantier, the artistic brother of Nana, the genius of the degenerate Rougon-Macquart family.

Atavistic tendencies explain the appearance of artistic powers during insanity as the result of a conservative tendency struggling with disease. A hypomaniac period sometimes so removes inhibitions of early training that difficulties are ignored and a seemingly mediocre artist executes a good work. PAOLI reports the case of an insane artist whose copy of a Madonna of RAPHAEL, painted during an attack, gained a prize medal at the exhibition. It is evident from the relative infrequency of artists among the English-speaking insane, as compared with the mechanicians, that a conservative factor has much to do with the appearance of artistic "sports" among the insane. The influence of the same factor is evident in the relative frequency of the insane with artistic tendencies among the patients of the insane hospitals of the Italian districts which have furnished most artists. It is also demonstrable in the atavistic effects of disease on artists who become insane. ANDRIANI found that four out of eight acutely maniacal painters retained their skill during the attack. In two, bizarre ideas appeared, while the work of two more markedly deteriorated, so much so, that in one instance the patient bitterly deplored after his recovery the work done during his insanity.

Paretic dement artists lose all sense of proportion; they begin to stretch trees which, if drawn in their entirety would pass beyond the frame. Exaggeration pushed to the improbable and even the impossible characterizes paretic dementia art, according to REGNARD. One of his patients painted a man whose head touched the stars while his feet were on the earth. As LOMBROSO forcibly points out in the "Man of Genius" paretic dement art effects are generally due to amnesia. Paretics often omit essentials from this cause. In a case observed by FRIGERIO a paretic dement drew a picture of a general seated, but forgot the chair. SIMON had under care a paretic dement who believed himself to be a second HORACE VERNET, yet drew horses with four strokes and a tail.

The most salient characteristic of art in mania is, according to LOMBROSO, **absurdity in** drawing or coloring due to exaggerated [illegible] of [illegible] throug which the connecting links that would serve to explain the author's meaning are lost A maniac artist painted "The Marriage at Cana of Galilee " He drew the "Apostles" excellently, but in place of Christ put a large bouquet of flowers The existence of an archaic symbolism is here apparent A periodic lunatic, during the paralucid intervals, painted fairly but with excessive minuteness During the attacks this minuteness became grotesquely exaggerated

According to Ruskin, the grotesque in art is divisible into three kinds Art arising from healthy but illogical play of imagination in times of rest, art arising from irregular and accidental contemplations of terrible things or evil in general, and art arising from the confusion of the imagination by the presence of truths which it can not perfectly grasp All these types of the grotesque are found in the insane, particularly the last two The first is rare, but it does exist Since art, an early acquirement of the race (as witness the Dordogne caves), is less affected by insanity than later acquirements it results that insanity at times merely tinges art Thus a periodically insane Italian mason became a painter when a patient at the Pesaro insane hospital His attacks were always announced by a tendency to caricature the hospital staff, whom he condemned in effigy to strange punishments The cook offended him, whereupon he painted the cook as a stout, ruddy man in the attitude of an *ecce homo* behind a grating which prevented him from touching the appetizing viands placed before it A patient of Dr Virgilio drew an excellent portrait of a maniac *in furore* Mancini, after his recovery from insanity, painted a Woman Offering for Sale a Picture Painted by a Lunatic " Magnoni had remained for fourteen years listless and idle in the Reggio insane hospital Dr Rani induced him to paint, whereupon he covered the walls of the ward with excellent frescoes One of these depicted the story of Ugolino so vividly that a patient threw meat to the father and children to prevent them from starving According to Magnam, Gill came of a family rife with apoplexy and degeneracy Like degeneratively-tainted dements, Gill had seemingly perfect lucid remissions During one of these remissions he sent to the "Salon" a picture of a melancholiac with depressing delusions crouching in one corner of a seclusion-room in an insane hospital Later he sent to the "Salon " "Salome with the Head of John the Baptist in a Charger " The decapitated head was his own, the plate was simply twenty-franc pieces joined by their edges The symbolism here evident was certainly not of a purely insane type

Many artists who have ranked high have exhibited elsewhere than in art their insane taint While Arreat claims that Leonardo da Vinci and Michael Angelo were on the "sane" side of the border line, he points out that they exhibited peculiarities Da Vinci had inchoate persecutory delusions, to which in no small degree were due his errabund tendencies Independently of Michael Angelo's sexual inversion, he had more than one hallucination He deserted his post in Florence in 1529 when it was beseiged by the imperialists He thus accounted for this performance to Della Porta

> How did I quit Florence? It is a problem I can not solve A man came to conduct me to the bastion There we examined everything, and a voice murmured in my ear, "There is nothing here for those to do who wish to save life and honor " Whether God or the Devil impelled me I can not tell

Turner exhibited degenerative taint, while Hayden, Landseer and Romney became insane The greatest artist of the English speaking countries who had a decidedly degenerate insane taint must be admitted to be Blake, who was the son of a hosier, and, like Turner, was of stunted growth In his youth he exhibited a genius for art and poetry When a boy, in his father's shop, he drew pictures on the counter and wrote poetry on the backs of bills He was moody, mystical and led a life of dreamy abstraction He had hallucinations of hearing, celestial voices called him He became an engraver, but wrote poetry copiously Between his twelfth and fifteenth years he had written seventy pages Visual hallucinations of poets, heroes and princes occurred, which he accepted as real His designs were revelations which he was commanded to publish by celestial voices He claimed that from his dead brother he learned that truly beautiful *and original method used in engraving and tinting* his plates This spirit counselled him as to the treatment of his best known and most successful works, "Days of Innocence " "Write, ' said the spirit, "the poetry, and draw the designs on copper with a liquid (which Blake always kept secret), then cut the plain parts of the plate down with aquafortis This will give the whole, both poetry and figures, in the manner of the stereoscope " Jesus Christ taught him how to mix his colors The "Gates of Paradise," another of Blake's works, ambitious in scope and quite incomprehensible, consists of twenty seven designs It is seemingly intended to embody the fall of Lucifer and the creation of man, and swarms with figures demoniac, human, and divine Blake's colossal egotism is evident in a letter written in 1800 to Flaxman

> I am more famed in Heaven for my works than I can well conceive In my brain are studies and chambers filled with books and pictures of old, which I wrote and printed in ages of eternity, before my mortal life, and these works are the delight and study of archangels Why then should I be anxious about the riches of fame or mortality?

Moses, Virgil, Dante and Milton are seen by Blake as "majestic shadows, gray but luminous, and superior to the common height of men " Blake's mind, as Allan Cunningham remarks, at all times resembles the page in the magician's book of glamour which made

> The cobwebs on the dungeon wall
> Seem tapestry in lordly hall

Blake's defects arose from the fact that he did not always clearly distinguish between the real and the ideal visualization His mind could convert the most ordinary occurrence into something mystic and supernatural He often saw less majestic shapes than those of the poets of old

"Did you ever see a fairy funeral, madam?" asked Blake of a lady "Never," was the reply "I have," said Blake, "but never before last night I was alone in my garden There was great stillness among the branches and flowers, and more than common sweetness in the air I heard a low and pleasant sound, and knew not whence it came At last I saw a broad leaf of a flower move, and underneath I saw a procession of creatures of the size and color of green and gray grasshoppers bearing a body laid on a rose leaf, which they buried with songs and then disappeared It was a fairy funeral"

He talked, as Ireland remarks, familiarly with his supernatural visitors The specters that entered his room were used as models He would look at them a while, then draw a little and then look up again Sometimes he would stop at his work, saying that the spirits had walked off Once he drew King Saul in armor, but could not finish the helmet because from the way Saul was standing he could not see the whole of it Some months after, the specter of Saul came back, and obligingly stood in such a position that Blake could sketch the helmet Once he was employed to furnish a likeness of Sir William Wallace In the presence of his employer Blake cried out "Sir William Wallace there—there I see him in all his glory" He commenced to draw, but suddenly paused When asked why, he replied "I can not finish him Edward I has stepped in between him and me" "That is lucky," responded his employer, "for I want him also" Blake sketched the Plantagenet on a sheet of paper, whereupon his majesty politely gave place to Sir William Wallace Blake's rapid visualization of correlated association was often present A friend of Blake, who collected several of his sketches which illustrate this same peculiarity, once remarked

> Observe the poetic fervor of that face It is Pindar as he stood a conqueror in the Olympic games This lovely creature is Corinna, who conquered in poetry at the same place That lady is Lais, the courtesan With the impudence which is part of her trade she stepped in between Blake and Corinna and he was obliged to paint her to get rid of her

The most grotesquely curious of Blake's visions was his "ghost of a flea," anent which Allen Cunningham cites this history

> This is the greatest curiosity of all Only look at the splendor of the coloring and the original character of the thing You see a naked figure, with a strong body and short neck, with burning eyes which long and moisten, and a face worthy of a murderer, holding a bloody cup in its clawed hands, out of which it seems eager to drink You never saw any shape so strange, nor did I ever see any coloring so curiously splendid—a kind of glistening green and dusky gold beautifully varnished It is the ghost of a flea, a spiritualization of the thing

Blake one evening was more than usually excited and told the friend he had seen a wonderful thing—the ghost of a flea "And did you make a drawing of him," the friend inquired "No, indeed," he replied, "I wish I had, but I shall if he appears again' He looked earnestly into a corner and said "Here he is, reach me my things, I shall keep my eye on him There he comes, his eager tongue whisking out of his mouth, a cup in his claw to hold blood, and covered with a scaly skin of gold and green"

The more demonstrably insane productions of certain artists display this symbolic tendency to find the occult in the real Like another insane artist of less genius but greater suspicional delusions, Benjamin Haydon, Blake appealed to the general public with an exhibition of designs chiefly "of a spiritual and political nature" But (Allen Cunningham) the spiritual work and political notions of Blake were unlike those of any one else One piece represented "The Spiritual Form of Newton Guiding Leviathan," and another "The Spiritual Form of Pitt Guiding Behemoth" Those who missed instruction in his pictures found entertainment in his catalogue, which was a wild performance overflowing with oddities and dreams and evidently an enunciation of Blake's notions of the laws of art Anent color Blake remarks

> Coloring does not depend on where the color is put on, where the lights and darks are put but all depends on form or outline Where that is wrong coloring can never be right, and it is always wrong in Titian, Correggio, Rubens and Rembrandt Until we get rid of them we shall never equal Raphael and Albert Durer, Michael Angelo and Julio Romano Clearness and precision have been my chief object in painting these pictures, clear color, and firm determinate lineaments unbroken by shadows, which ought to display and not hide form, as is the practice of the later schools of Italy and Flanders Oil has been falsely supposed to give strength to colors, but a little consideration must show the fallacy of that opinion Oil will not drink or absorb color enough to stand the test of any little item and of the air Let all the works of the artists since Rubens' time witness to the villainy of those who first brought oil painting into general opinion and practice, since which we have never had a picture painted that would show itself by the side of an earlier composition This is an awful thing to say to oil painters, they may call it madness but it is true All the genuine, old, little paintings are in fresco not in oil

Those "abominations concealed outlines and tricks of color," bringing on one of those visionary fits to which Blake was liable, he narrates with the most amusing wildness sundry revelations made to him anent them Certain painters, according to Blake, are demons let loose on earth to confound the sharp, wiry outlines and fill men's minds with fear and perturbation. He admits that he himself was for some time a miserable instrument in the hands of "chiaroscuro demons," who employed him in making "experiment pictures in oil." Anent which he writes:

These pictures were the result of *temptations* and perturbations, laboring to destroy imaginative power by means of that infernal machine called chiaroscuro in the hands of Venetian and Flemish demons who hate Roman and Florentine schools. They cause that everything in art shall become a machine; they cause that the execution shall be all blocked up with brown shadows. They put the artist in fear and doubt of his own original conception. The spirit of Titian is particularly active in raising doubts concerning the possibility of executing without a model. Rubens is a most outrageous demon, and by infusing the remembrance of his picture and style of execution, hinders all power of individual thought. Correggio is a soft, effeminate, and consequently most cruel, demon, whose whole delight is to cause endless labor to whoever suffers him to enter his mind.

Titian was, however, the most malignant of his persecutors. He told Charles Lamb that all the while he was engaged on his water painting, Titian was disturbing him—Titian, the evil genius of oil painting. Blake's intense belief in his mentally reached visions was so infectious that, as Allan Cunningham remarks, some acute and sensible persons who heard him expatiate, shook their heads and hinted that he was an extraordinary man and there might be something in the matter. His wife, a modest, loving, intelligent but not highly educated woman, accepted the truth of all his visions. As so often happens with paranoiacs, *folie-a-deux* resulted, but, as Blake's persecutors were in the ideal world, no serious consequences followed. Blake's mental defect showed itself in his inability to distinguish the objective from active reproductions of the memory. He partially recognized the mental origin of some of his visions. "The other evening, taking a walk," said he quietly, one night, "I came to a meadow, and at the farther end of it I saw a fold of lambs coming nearer, the ground blushed with flowers and the wattled cote and its woolly tenants were of an exquisite pastoral beauty. But it proved to be no living flock, but beautiful sculpture." A lady present thinking this a capital holiday show for her children, eagerly interposed, "I beg pardon, Mr. Blake, but may I ask where you saw this?" "Here, madam," answered Blake, touching his forehead.

As a rule, however, productions of Blake's visualizing powers were facts to him, not mental visions, whence the incomprehensibility of much of his work. When the fact element is uppermost, puerile minuteness and repetition mar the work. The bathos of insane egotism swamps the artist.

Let us have a Department of Public Health!

THE HYGIENE OF MUSIC AGAIN

Some little time ago this journal editorially called attention to what, in a medical point of view, appeared to be some insalutary possibilities of the over-encouragement of musical culture, and in so doing noticed briefly some of the theories of the origin of the musical sense and emphasized a little the fact that it is essentially a sensuous and emotional faculty, not in any intrinsic sense an intellectual one. An esteemed correspondent has found in the said editorial, matter to which he strongly objects, and accuses us of over-magnifying the value of the merely useful, and under-estimating that of the higher incitants of the imagination. As he appears to have misunderstood the whole spirit and tenor of the editorial referred to, it may be well to take up the subject again and state, it may be more plainly, the idea it was intended to convey.

There is no rational being that can honestly deny the utility of the pleasures of life, and music is certainly one of the highest of these. This, however, does not alter the fact that excessive indulgence in any of them not only may be, but must necessarily be, harmful to the individual, and that this is true as well of those that are usually reckoned as higher and more refined as of the grosser sensual appetites and tastes. The difference is mainly one of degree; music does not necessarily or always refine the disposition, and natural brutality may be aggravated by undue emotional excitation in this way as in any other. It does not tend essentially to improve morals any more than intellect, in spite of what Dr. Mettler says there are more than there should be among musical celebrities who have been deficient in the former, and the intellectual giants among them are few and hard to find.

It is not with intellect or morals, however, that the medical interest of the question of the hygiene of music has mainly to do; the point in the editorial referred to was the possibility of its excessive culture inducing morbid developments in impressible subjects, a danger which, it is believed, has been too much overlooked. The question was also raised whether this danger was not augmented with the popularity of certain modern types of music, more particularly that of Wagner and his followers, the cult of which seems to fall in well with the various "intensity" fads lately in vogue. The emotional erethism incited by some of this modern music must, judging by the language of some of its devotees, be something altogether beyond the comprehension, not to say the appreciation, of the uninitiated. As was said before, their descriptions suggest more than anything else a perversion of a sense and a morbid, unnatural enjoyment. It may not be scientific to quote Nordau, but there may be more truth than poetry in his characterization of the present dominant spirit in music as a symptom of degeneration. The classic masters of the earlier half of this century would hardly sympathize with it, if a Mendelssohn could not enjoy a Berlioz or a Liszt, he could hardly endure a Wagner or a Rubinstein

The pathologic possibilities of music are not confined, however, to to the higher-grade music of the concert-room or opera, but may be found in the simplest melodies, anything that can thoroughly stir up the emotions possesses them It would obviously not be a wise thing to constantly play the Ranz des Vaches to a Swiss mercenary, or "Lochaber no More" to a Highland exile The over cultivation of music by some impressible individuals has had disastrous effects, its results have been observed in asylums for the insane, and any too general and indiscriminating tendency this way, it is not hard to believe, may have general bad results, if we can credit such an observer as Lawson Tait

The dancing mania of the middle ages is a fair example of misguided and misdirected musical and religious enthusiasm

It does not follow that because one is able to see these possibilities, he has lost his appreciation of the beautiful, or has been reduced to the level of bald Gradgrind utilitarianism Nor does the recognition of the fact, for such it is, that the musical faculty is essentially not an intellectual one, imply that the individual has no musical taste or capacity for enjoyment of sweet sounds Life without its pleasures would be a hard thing to endure, but, as physicians, we should not shut our eyes to the misuse of even excellent things when it concerns our bodily salvation

CORRESPONDENCE

The Association and the Colleges

Trenton, Tenn , Sept 12, 1898

To the Editor —I have before me Dr D S Reynolds' reply to my note on page 547 of the Journal When I presided over the Association in Denver, I acted *then* in my official capacity, *now* I am only a member of the American Medical Association, and as such have a right to criticise any of its actions In the hurry of business, a presiding officer puts such motions as are made, if they are not plainly out of order, when no point of order is made against them, just as was done in the resolutions offered by Dr Hare in regard to the admission of the members from the State of New York, who were not in affiliation with the recognized Society in that State The question was discussed at some length before the point of order was made against it that it was out of order because it involved a change in our Constitution in regard to membership The chair at once ruled the question out of order, and no appeal was taken A legislative body frequently passes an unconstitutional act, and it is so declared by our courts of last resort The "Court of Last Resort" in the American Medical Association is the Association itself, and the fact that a matter has been adopted, even by a vote in which there were no negative votes cast, does not make it legal I do not plead ignorance of law Those who know me best know that I *never* make that plea It is the *knowledge* of law that I am pleading, and that very fact has induced me to call up this matter Any one at all posted on law knows that no by law can be passed which contravenes the constitution or charter which it interprets All by laws, or if Dr Dudley prefers the expression, ordinances, must conform to the charter or constitution, or they are unconstitutional, and hence not binding An unconstitutional act can not be enforced The constitution alone can fix the qualifications for membership, and any attempt to change this qualification is an attempt to alter or amend the constitution, and must be treated as such To amend our constitution, only one way or method of procedure is laid down, and that is found on page 9, section 7, "Provision for Amendment," already mentioned in my first communication The specifications to which Dr Dudley refers in the by laws conform to the constitution of the American Medical Association, but this new action of the Association at Denver in regard to the colleges, goes beyond the requirements of the constitution for membership and hence is void

There can be no "technical quibble about attempting to make the resolution appear as an amendment to the constitution" It is either an effort to amend, or it is not There is nothing "technical," nor is there any quibble It is a straightforward presentation of the facts in the case It is certainly in the province of the Association to fix any requirements for membership it may see fit, but this must be done in a legal way The object of the constitution in requiring one year's notice of such proposed amendments is too plain It is to give notice to all interested in the matter, so that "the unexpected" may not happen

Dr Dudley is unfortunate in his reference to the law in regard to amending the by laws The order of business is a by law itself, and the provision, to which reference is made, only relates to that one special by law providing for changes in the order of business so as to allow the Association by a three fourths vote to take up any special item and consider it, regardless of the order of the call This provision is as it should be, because without it unfinished and miscellaneous business (Sec 15) might never be reached As to the standard of qualifications for the practice of medicine, each State is regulating that, and a diploma of a college demanding five courses would have no more weight than would one issued by a college requiring two or three courses only With that the Association has nothing to do The Association has a right to fix, and can fix in a *legal* way a standard for admission into the membership of the American Medical Association, but it can not say what "can be accepted of any candidate for admission to the regular medical profession of the United States" The code of ethics governs admissions into the ranks of the regular medical profession

I do not propose to be drawn into a discussion in regard to the number of terms that may be necessary for students to acquire a sufficient amount of medical lore to enable them understandingly to begin the practice of medicine It can be summed up in one sentence Some who attend medical schools *never* learn enough

I am not a college professor, nor am I related by "affinity or consanguinity" to any one connected with a medical college, and hence what I say or do in this matter can not be due to college bias

T J Happel, M D

The Medical College Resolution

Nashville, Tenn , Sept 12, 1898

To the Editor —In a communication from Dr Happel, which recently appeared in the Journal, I learn that he was misled by a statement made by the Secretary of the Business Committee, when he reported on the medical college resolution Dr Bulkley had no authority to state that the Southern Medical College Association, through one of its members, had given assent to the resolution I was the member referred to and certainly did not say anything that would justify the statement made by Dr Bulkley I did appear before a com

mittee of the Executive Co did also ley

Reynolds, a member of the cil of t n

College Association. I stated to the committee that the Southern College Association would take final action at its next annual meeting, which would be held in Memphis in November next, on an amendment to the constitution looking to the establishment of a four years' graded course. I further stated that I had no reason to believe otherwise, than that this action would result in the establishment of the four years' graded course, thus placing the Southern colleges on the same plane with the colleges of the American College Association. I argued that those students who had matriculated in our various colleges, prior to this change in the constitution would be entitled to graduate at the end of three years, and asked that the resolution be modified so as to allow our colleges this privilege. The sub-committee would not listen to so long an extension of time. Finally the conclusion was reached that the class of 1898-99 could be graduated at the end of the third year, and not affect the membership in the American Medical Association of individuals connected with these colleges. I saw that this was the best that could be done, and then it was that I said: "If, in your report, you make it appear that the Southern colleges are not being driven in this matter I will not fight the resolution; but if you do not make it so appear then I will be forced, in the interest of the Southern Medical College Association to do my best toward defeating the resolution." I was present when the Executive Committee made its report, through its Secretary, and was surprised as to the manner in which the report was made; but seeing that the intention of the Secretary was to show that the Southern colleges were not being driven, to comply with my promise not to fight the resolution, I said nothing.

Up to this time it had not occurred to me, and it seems that it had not occurred to any one else, that the whole thing was out of order, or I should have raised that point, which, if sustained by the presiding officer, would have delayed final action for one year.

Dr. Reynolds' reply to Dr. Happel's communication is beyond all doubt incorrect. So vital a thing as the question of membership of an organization would not fail to be included in the constitution of such an organization. The matter of "membership" and "rules of order" are very different things; the latter always being in the by-laws, the former always in the constitution. By-laws, and resolutions not intended as law at all, when in conflict with the constitution of any organization, would certainly be null and void. An amendment to the constitution of any organization should never be rushed rapidly through to final action. Hence the very important feature of all constitutions is that they can not be changed without some due consideration, and after an interval of time longer or shorter. Such an amendment must always refer to the article and to the section to be amended.

Dr. Reynolds ought to know, and I presume he does, that Dr. Happel's statement touching the unconstitutional nature of the resolution, could have only the force of a non-official member of the body, but that the opinion expressed by Dr. Happel is correct, no one who is unprejudiced in this matter can doubt. The Judicial Council is the body to which this resolution will have to be referred at the next annual meeting. If this Council finds the resolution to conflict with the constitution of the American Medical Association, their decision can be but one thing, and that is that the resolution is null and void.

With the present feeling in the Association there could be no doubt but that an amendment to the constitution, similar to the resolution that was passed in Denver, will be introduced in proper form, at the next meeting, and that it will be finally acted on favorably, at the annual meeting in 1900. In the meantime the colleges constituting the Southern College Association will have carried out their original intention of extending the course of medical instruction to four years. The amendment was introduced two years ago, and would have been acted on finally at the annual meeting in May 1897, except for a request from Tulane University (whose delegate was unable to attend because of the flood) that final action be deferred until the next meeting.

G. C. Savage.

A Case in Obstetrics

Sioux Falls, S. D., Sept. 10, 1898.

To the Editor:—On responding to a call in the country, July 24, to attend Mrs. S. in confinement, I found myself confronted with complications different from anything I had ever before encountered.

I reached the home of my patient, about seven miles from town, about noon. She was a large, muscular woman about 42 years of age, living with her second husband. She had given birth to ten children by her first husband, the oldest now 19 years of age. She had also had three miscarriages, one since living with her present husband.

I found her in bed, lying partially on her right side, with head and shoulders raised by pillows and her lower extremities elevated, because of a violent hemorrhage which had taken place. She was sweating profusely, was very cyanotic, with painful dyspnea, was coughing incessantly, raising enormous quantities of thick, tenacious mucous of a pinkish tint. Pulse 120 and irregular. Inspection revealed a very large abdomen, with very lax walls, so that the uterus and contents would roll from side to side, as she turned. There was complete inertia of the uterus; it seemed large enough to contain twice its contents. A digital examination brought on a profuse discharge of dark, stale, foul smelling clots. I was unable per vaginam to make out the presentation, but by external manipulation decided it to be a breech. I had never before found a fetus so movable in utero; it slipped about so freely that I would sometimes find the breech and sometimes the head presenting, perplexing me not a little. I could make out no fetal heart-sounds, so decided we had a dead fetus to deliver, though the mother insisted motion had continued up to that time and that she could still feel it. On close questioning, she admitted that up to just four weeks previously movements had been strong, painful and annoying, but for the past four weeks had been slow and gentle. Knowing that a dead fetus will roll about enough to simulate motion, I thought nothing of this. She stated that about 2 o'clock, A.M., she had felt a desire to urinate and got up upon the chamber, when the membranes ruptured and nearly filled the vessel with a very dark brownish liquid. A neighboring midwife was sent for, who on her arrival became alarmed at the large quantity of dark, foul smelling clots that were coming away, recommended that a doctor be sent for. Any attempt to manipulate the uterus to excite contraction, or to introduce my hand into the vagina, would greatly aggravate the cough and dyspnea. Patient appeared much alarmed, complained of the dyspnea and said she felt as though her lungs were filled up "clear to the palate." Loud mucous râles could be heard all over the chest. Not deeming it safe to administer an anesthetic, I gave her a teaspoonful of ergot, together with ¼ grain of extract of belladonna, ¼ grain of codein, and six drops of chloroform. In an hour I gave her half a teaspoonful of ergot and repeated the belladonna and chloroform, omitting the codein. The cough and expectoration subsided, the dyspnea disappeared, hemorrhage stopped and pulse came down to 100. Within an hour after the second dose she was able to turn upon her right side and, with pillows removed, rest quietly. Previously she had been unable to lie either upon her right side or back. The uterus began to contract feebly, but regularly, though any attempt at manipulation would bring on the cough and dyspnea. I then administered a three grain pill of ergotin and a two grain of quinin and awaited developments. Pains grew more frequent and regular until about 11 P.M., when they became strong and natural

Introducing two fingers into the vagina, I now succeeded in hooking into the groin of the fetus and delivering it promptly It had the appearance of being somewhat immature and of having been dead a long time The secundines were delivered in the usual manner in about twenty minutes

My attention was attracted to the extreme length of the cord Upon examination, I found a large, firm knot near the center, revealing the cause of the death of the child It was not simply a single knot, but a complete figure 8 The cord had apparently become looped, twisted once upon itself and the loop had passed completely over the fetus and been drawn tight, shutting off the circulation Untying the knot and measuring the cord I found it to be *forty seven* inches long, by careful measurement Forty inches is the longest I had ever before found After the removal of the placenta and clots the uterus contracted normally and the patient felt relieved of all her distressing symptoms

My theory, which may not be correct, is that after the cord became tied the placenta was detached and hemorrhage took place, distending the uterus abnormally, finally being limited and controlled by the size of the uterus, and for some reason it could not escape from the os, the clots remaining in utero until after the rupture of the membranes, when they were allowed to escape The cough, with profuse expectoration, the dyspnea, cyanosis, perspiration and high pulse were, I believe, due to absorption of toxic material from within the uterus I report the case, hoping it may be as interesting and instructive to some of the readers of the JOURNAL as it has been to the writer

A H TUFTS, M D

Braces in Spinal Curvature

CHICAGO, Sept 12, 1898

To the Editor —In the JOURNAL of Sept 10, 1898, there appears an editorial entitled "Braces in Spinal Curvature" which contains so many half truths, to put it gently, that it should not pass without comment

The editorial writer says "The two conditions of tubercular caries and spinal curvature differ so widely in their causation, symptomatology and treatment that each must have a clear cut picture in our mind when examining soinal caries " This is true in so far as causation and treatment go, but it is not true in all cases in so far as symptomatology is concerned It is true that there are cases that distinctly differ, and there are other cases where those having the greatest experience can not at once differentiate Lateral spinal curvature may not simulate tubercular caries, indeed there would be no serious harm done to the patient by the treatment if it did, but tubercular caries in the early stage, before the characteristic posterior deformity has developed, may simulate spinal curvature so closely that a certain diagnosis can not be made by any one on the first examination This is a serious matter, for tubercular caries will be seriously aggravated if it be treated for spinal curvature In all cases of doubt the benefit of the doubt should be given to tubercular caries, and the case treated by some efficient form of immobilizing apparatus

Now as to symptoms A reflex rigidity of the spine is the only constant symptom in tubercular caries Pain is rarely present until months after a diagnosis should have been made, and in many cases it is never complained of during the entire course of the disease Pain on motion is rarely present except when the patient is caught off his guard The involuntary muscular rigidity, above referred to, protects the spine from motion, which otherwise would be painful It is a very fatal error to regard pain as a constant symptom in tubercular caries of the spine or of other bones I have reported a case of hip disease that passed to a flexion deformity of ninety degrees and absolute loss of motion, then through a complete reduction of the deformity by a leverage brace, through the development and spontaneous evacuation of two large abscesses, and finally to recovery with good motion at the end of six years, that never had a minute's pain or tenderness, and was all the time able to walk on the leg and also to stand on it alone, and holding up the well leg, hop about without the slightest sensitiveness "Angular deformity in an anteroposterior plane" is a comparatively late symptom, he who can not make a certain diagnosis long before the development of "angular deformity in an antero posterior plane," is very ill fitted to treat a case of tubercular caries of the spine Lateral deformity, simulating lateral curvature, is an early symptom in nearly half of the cases Abscesses appear in less than half of the cases and paralysis, fortunately, is very rare These should be counted as complications and not as symptoms of tubercular spinal caries If the diagnosis is made early, tubercular caries of the spine will be found in well nourished as often as in ill nourished children, it is only when it has remained unrecognized for months, perhaps until pain is complained of and angular deformity has developed, that the children nearly all become poorly nourished

As to lateral curvature of the spine It has not been demonstrated by any one that the predisposing causes are prolonged ill health or rapid growth As a rule these cases have not grown rapidly, they are undersized, and have never had any special ill health, prolonged or otherwise It is true that it is usually noticed by the dressmaker, between the ages of twelve and twenty years, but it can be found, if looked for, many years earlier, as shown by Ketch of New York No one has shown any hypertrophy in the muscles of either side, if it were on either side it could not be on the side of the convexity, as claimed by your editorial writer, and further, it has been clearly proven by Scudder, of Boston, that there is no muscular hypertrophy, or atrophy, or muscular weakness, or difference in the strength of the muscles of the two sides in the ordinary cases of lateral spinal curvature A tilted pelvis arises from a short leg, and one short leg is found in sixty per cent of children who have no lateral curvature, as was long ago shown by Morton, of Philadelphia When there is a short leg and a tilted pelvis in conjunction with lateral curvature it is found quite as often on the wrong side as on the right side That is to say, with a right dorsal and left lumbar curvature the pelvis should be oblique, the right side high and the left low, and the left leg shorter than the right Quite as often as otherwise the right leg is half an inch shorter than the left, as reported by me many years ago, and since confirmed by many observers A word as to the treatment In slight cases, especially in postural cases, "apparatus," that is, braces and corsets, is not necessary In cases where there is any of what Roth calls "osseous deformity" "apparatus" is necessary if reduction of deformity is to be gained, and often, if the progress of the deformity is to be checked, but the "apparatus" should always be used in conjunction with exercises given by the surgeon himself

Respectfully yours,

JOHN RIDLON

American Public Health Association—Twenty-Sixth Annual Meeting

CHICAGO, Sept 12, 1898

To the Editor —The forthcoming meeting of this Association is an international one, inasmuch as it will convene at Ottawa, Canada, Sept 27 next, and as such promises to be of much interest, because representatives, not only from the United States, but from Mexico and Canada will be present

As this Association has been known in the past for its marked energy in successfully promulgating Municipal, State, National and International sanitary matters, its influence in disseminating the practical application of public hygiene, not only to the medical profession of the countr
the public generally will be wide It ap
that at this particular time our professi
represented at this international meeting

well known that all the wisdom of sanitary science is not contained in a few hundred of the members of this or any other large body, but there are other important reasons why this meeting should be a representative one in numbers, namely among the special committees provided for in its constitution, is the Committee of Public Health Legislation, and it is expected that this committee will submit a comprehensive report, on the merits of which a full discussion should be participated in by medical men

The convening of Congress at Washington, next winter, will be awaited with renewed interest, as many important topics of a judicial and commercial nature will be introduced, of which none are more important than public health matters With the strong endorsement of the AMERICAN MEDICAL ASSOCIATION, the American Public Health Association, and scores of other scientific societies throughout the United States, our profession should *demand* of Congress that our petition looking toward a Department of Health be granted—a department that will be an ideal one from which any country throughout the universe might model

As the medical profession and citizens of the beautiful and picturesque capital city of the Dominion of Canada have invited this Association and its friends to be their guests at this meeting, it is hoped that a large representation of our profession can attend Several entertainments have been provided for Those of us who have shared their hospitality on similar occasions know the social functions extended to us, and their unbounded hospitality is proverbial For this occasion complimentary excursions, luncheons, etc , have been announced on the program, and the ladies who will grace the gathering will be provided for in a charming manner

The usual rate of a *fare and a third* has been granted by the railroads tickets issued on the certificate plan It is proposed to leave Chicago on Sunday, September 25, at 3 15 P M , via the Wabash and C P R The magnificent sleepers of the Canadian Pacific will run through from Chicago to Ottawa without change It is expected that the Mexican delegates will go this way, thus accompanying those who pass through and depart from Chicago The train leaving Chicago at 3 15 P M , is due to arrive at Detroit at 10 45 P M on Sunday, when we will be joined by other members of the Association, who will accompany us the remainder of our journey Leaving Detroit at 11 35 P M , we are due at Toronto on Monday morning the 26th, and at Ottawa at 5 P M the same day

Believing that this international meeting will be an unusually profitable one, scientifically, and that a large attendance is particularly desirable, is why the writer has invoked space in our JOURNAL for this communication

Very sincerely yours,
LISTON H MONTGOMERY

PUBLIC HEALTH

Society for the "Repression' of Tuberculosis —A well attended meeting of prominent members of the profession took place recently, by invitation, at the house of Sir William Broadbent The meeting had been called to consider the advisability of inaugurating a movement to disseminate knowledge concerning tuberculosis and its prevention, and also the provision of sanatoria for the open air treatment of tuberculous lung disease Sir William Broadbent was in the chair, and he briefly stated the objects in view He read a letter from the President of the Royal College of Physicians of London, expressing approval of the project and suggesting lines of work Dr Corfield, Mr Malcolm Morris, Mr Shirley Murphy, Dr Isambard Owen, Dr J Pollock, Dr Ransome, Dr H Weber and others spoke, and resolutions were passed 1, expressing the desirability of forming a public association for the purpose stated, and 2, appointing a provisional committee to take the necessary steps to start such an association We heartily sympathize with any action which may be taken to diminish the amount of tuberculous disease, and consider that if, as no doubt will be case, the methods of effecting this are pursued with wisdom and discretion, much good will be done The facts, as stated by Dr Ransome, that under existing sanitary legislation the death rate from such disease has been reduced by two thirds, and, as Mr Shirley Murphy pointed out, that vast improvements have taken place in London habitations during the past twenty years, go far to encourage the hope that yet greater benefits will accrue when the community realize fully the preventable nature of tuberculosis and the value of pure air and food —London *Lancet*

Phosphorus Poisoning in France —The prevalence of this formerly serious evil has been much reduced since the French government assumed the monopoly of match manufacture, and framed rules that must be read aloud to the work people at the factories, at least once every month Among these rules, according to the London *Lancet* for August 6, is one that enjoins that no food or drink shall be allowed in the work shop, but must be left in the dining room, that before meals the working clothes must be left in the cloak room, and the work people must wash their hands with soft soap and water, and must gargle their mouths with a gargle specially provided for that purpose Then only are they allowed to eat The same precautions are taken on their leaving the works Further, it is enacted that no one shall be employed under sixteen years of age, and that they must first be examined by the medical man, who must certify that they are free from bodily infirmity and contagious disease, that they have been vaccinated or have had smallpox, and that the state of the teeth is good As a result of these precautions among the 575 men and women employed at the Pantin and Aubervilliers works there has not been a single case of phosphorus poisoning during the year 1897 A reduction in the severer cases has been chiefly due to raising the age of admission, to medical examination, subsequent close supervision, repeated dental examination, the personal cleanliness of the workers, and immediate suspension on first symptoms of illness, with allowance of two thirds of the salary while the employé is away from the works The French government is doing all in its power to discover better methods of manufacture Chemists and inventors are paid out of the public purse to study the matter, and the result is, that a match which will strike anywhere and yet which is free from phosphorus has been invented, though it has not yet become a commercial article

Milk Supervision by Municipal Sanitary Boards —Dr W H Hatch has reported in the *Journal of Comparative Medicine*, some of the good results of local milk work in the city of Buffalo, N Y

In the absence of State supervision it would seem pertinent to here refer to the system adopted by the Health Commissioner of Buffalo, with the view of mitigating, if possible, the contamination mentioned By his direction a record of the various dairies supplying the city is kept This includes inquiry 1, as to the herds, their health, and whether they are subjected to veterinary examination and tuberculin test, 2, the methods of cleaning utensils, the process and time given for cooling the milk, hour of shipment, and distance hauled, 3, quality and source of the water supply, 4, physical condition of the employes, etc , 5, educational efforts in the way of causing the dissemination of literature bearing upon the interest of the dairyman and his care of the milk

Following this, where conditions at the dairy are deleterious or where circumstances arise of a character deemed prejudicial to the public health, instant investigation by the health department is made, and the dairyman required to correct, without delay, such conditions as may be at fault Failing to do which, or even prior to notification, if urgency and facts demand it, the product of such dairy is interdicted at the city line, the milk house in the city to which the milk is consigned being at the same time notified and prohibited from receiving the milk, under penalty of the revocation of license Under this system, the only one available under the circumstances, it is believed that decided sanitary improvement has been made in the dairies supplying Buffalo, the ratio of infection diminished, and a corresponding influence made upon the public health Many dealers keep milk only as a convenience to their customers Their facilities for proper storing and handling are insufficient—in fact, nothing This traffic in milk is objectionable from the fact that it is only a small part of the business, and subsidiary to other interests The average store keeper has little or no information relating to milk, which, while in the store, is not only liable to absorb deleterious odors from adjacent products, from vegetables, perchance decomposing, but more seriously to contamination by micro organisms, from dust and dirt which are tracked in from the street by the feet of customers and blown about the store by the draughts This condition is always present and a danger, and is invited by the habit of leaving the milk cans uncovered Grocers and other small dealers should be and are obliged, in Buffalo, to keep posted in a conspicuous place the names and license of those from whom they obtain their milk To abolish this store peddling will be difficult, but existing conditions should be mitigated by personal instruction to the dealers and frequent inspection by those designated for that duty Adulteration of milk by water or contamination by preservatives may be considered of secondary importance to the question of sanitation Stringent ordinances relating to both are proper Concerning the former, the use of the lactometer as a method of testing has given rise to much discussion through the possibility of evasion at the hands of crafty and unscrupulous dealers State and city laws upon this feature are too liberal, placing the standing as low as it has been deemed possible for normal milk to assume under ordinary conditions Adulteration of milk by water is not a common occurrence in Buffalo, and is seldom found among representative dealers It is in the main confined to peddlers, who, having an unusual and unexpected demand, resort to the Buffalo water supply for assistance The peddling of milk in the streets as well as the distribution of milk through grocery stores and small dealers should properly be abandoned The yearly license system, with power of revocation and with heavy penalties for violating ordinances relating to the business, and with further penalty of exclusion from the trade after a certain number of offences, should be adopted The features here specified are necessitated by the fact that in all municipalities the evils they endeavor to cover and prevent have been found to exist, and through their existence contamination has occurred, and disease has been definitely assigned to to them Almost all these directions are through the direction of Health Commissioner Wende, embodied in the ordinances of the City of Buffalo, and enforced without favor They have been found efficient, and the security they have given to milk has been demonstrated by the low rate of infantile mortality through diseases known to be due to milk

Anaerobic Bacterial Purification of Sewage—In the *British Medical Journal*, Dr Boyce directs the attention of sanitarians to some early attempts at the bacterial treatment of refuse, in part as follows "The most recent advance in the treatment of sewage was subjecting it to aerobic fermentation This now seems likely to be reinforced by an anaerobic method, and one which may play a most important part in the solution of a very difficult and costly problem I should like, therefore, to direct attention to some early work upon the subject which, as far as I am aware, appears to have been overlooked In January, 1893, my father received a very interesting letter from the British Consul at Barcelona, bringing to his notice a new method for the treatment of sewage, a method which the writer stated had been published in France about the year 1883 by the Abbè Moigno The Consul stated that the system had been tried by a well known merchant of Barcelona, at first at his factory and then at his private residence, and that at the time of writing the method had been in operation for five years with perfect success The Consul had himself inspected the tank and had seen the almost colorless and odorless fluid which came away, and which was removed in casks and employed for manure purposes without causing the slightest repugnance 'By a mysterious action which reveals an entirely new principle it transforms all that it receives, both solid and liquid evacuations, in a tolerably short time, and without any addition of chemic ingredients into a homogeneous and scarcely turbid liquid, which holds everything in suspension in a state of filaments almost visible, without leaving any deposit against the sides of the soil pipe or at the bottom of the drain pipe' The apparatus is constantly discharging, and the fluid is admirable for domestic irrigation The septic tank is then accurately described and figured, and the capacity calculated for the amount of work it has to do It is in effect the perfect septic tank as now understood The Abbè discusses the theory of action of the complete decomposition of the fecal and refuse material in the airless tank, and hints that it may be due to the action of a hydrosulphate of ammonia, but he adds that this is a conjecture, and proceeds, 'May it not be discovered that the mysterious agents of the fermentation, cause of the decomposition and liquefaction of the feces are the vibrios, or rather the anaerobes of M Pasteur, which the oxygen kills, and which only employ their devouring activity when excluded from the air?' A laboratory septic tank was constructed with glass sides, so that the whole process of fermentation and liquefaction could be observed, the layer of about 5 c c, which forms upon the surface is described and the manner in which it undergoes disintegration A tap was placed on the top of the tank and over this a bladder was securely fastened, and it was found that little, if any, distention of the bladder occurred If, however, air was admitted to the tank there was a rapid development of gas bubbles and soon the bladder was distended, and therefore for the effective working of the bacterial destructor it was essential to exclude the air He points out that a certain proportion of water is requisite to prevent saturation of the fluid with the product of decomposition, and in consequence arrest of the process Chemic analysis of the fluid showed that it possessed strong fertilizing properties The Abbè conjectures that during the petrid anaerobic fermentation any pathogenic germs which might be present are destroyed, and that therefore the fluid can be turned with impunity into the sewers or used for irrigation"

BOOK NOTICES

An American Text book of Gynecology, Medical and Surgical, for Practitioners and Students By Henry T Byford, M D J M Baldy, M D, Edwin B Cragin, M D J H Etheridge, M D, William Goodell, M D, Howard Kelly, M D, Florian Krug, M D, E E Montgomery M D, William R Pryor, M D, George M Tuttle, M D Edited by J M Baldy, M D Second edition, revised illustrated Pp 718 Philadelphia W B Saunders, 1898 Price, cloth, $6 sheep or half morocco, $7 For sale by subscription

Our notice of the first edition of this work will be found in Vol xxii, p 62, Jan 13, 1894 in which we gave a favorable notice of the work In this edition we are informed by the editor that more than forty of the old illustrations have been replaced by new ones, and the mat
been altered and oted
work are practically n rec

been rewritten and more fully illustrated. The book has been revised, so that it fairly covers the changes and improvements which have been made in the art during the four years which have elapsed since the publication of the first edition. The style of the work is excellent, the publisher having spared no pains to secure the finest typographic effect. Some of the illustrations are beautiful.

A Text Book Upon Pathogenic Bacteria for Students of Medicine and Physicians. By JOSEPH MCFARLAND, Professor of Pathology in the Medico Chirurgical College. With 134 illustrations. Pp. 497. Second edition, revised and enlarged. Philadelphia: W. B. Saunders. 1898. Price, $2.50 net.

Our notice of the first edition of this work will be found in Vol. xxvi, page 688, April 4, 1896, and we regret to see that the errors in history which were pointed out in our notice have still been continued in the present edition, no correction having been made. In other respects, the volume sustains the favorable opinion we gave of it on its first appearance. In this edition new chapters have been added, dealing with the bacteriology of whooping cough, mumps, yellow fever, hog cholera-swine plague, describing bacillus aerogenes capsulatus and proteus vulgaris, and pointing out the methods of determining the value of antiseptics and germicides, and of determining the thermal death point. This makes a work fully abreast of the times, and one of the most useful of recent text books on bacteriology, so far as its practical applications are concerned.

Onzieme Congres de Chirurgie, Paris, 1897, Association Française de Chirurgie, Procès Verbaux, Mémoires et Discussions Publiés sous la direction De M. Le Dr. LUCIEN PICQUÉ, Secrétaire Général. 8vo. Pp. 960, with numerous engravings. Paris: Félix Alcan. Price 20 f.

This work comprises the transactions, papers and discussions of the Eleventh Congress of Surgery, held at Paris in October last by the Association Française de Chirurgie. The questions which were discussed at this session were, first, "Contusions of the Abdomen," and, second, "The Indications for Operation and Treatment of Cancer of the Rectum." In addition to the numerous communications and discussions which belonged to the program there were also many volunteer papers presented by the members of the congress on interesting surgical cases. An examination of the volume shows conclusively that, from the standpoint of efficient surgery, the French surgeon still keeps on as high a plane as other leading surgeons of the world.

The Twelfth Congress will be held at Paris by the Faculté de Médecine on Monday, Oct. 17, 1898, under the presidency of Prof. Le Dentu.

An American Text book of the Diseases of Children, Including Special Chapters on Essentially Surgical Subjects—Orthopedics; Diseases of the Eye, Ear, Nose and Throat; Diseases of the Skin; and on the Diet, Hygiene and General Management of Children, by American Teachers. Edited by LOUIS STARR, M.D., assisted by THOMPSON S. WESCOTT, M.D. Second edition, revised. Pp. 1244. Philadelphia: W. B. Saunders, 1898. Cloth, $7; half morocco, $8; sale by subscription only.

There are sixty eight contributors to this volume. The contents of the volume are, in general, as follows: First, an Introduction of 60 pages; next, Part I, disorders incident to birth and diseases of the newborn, 68 pages; Part II, diathetic diseases; Part III, infectious diseases; Part IV, general diseases not infectious; Part V, diseases of the blood; Part VI, diseases of the digestive organs; Part VII, diseases of the nervous system; Part VIII, diseases of the respiratory system; Part IX, diseases of the heart; Part X, diseases of the genito urinary system; Part XI, orthopedics; Part XII, diseases of the skin; Part XIII, diseases of the ear; Part XIV, diseases of the eye.

The first edition of this book was noticed in this JOURNAL in Vol. xxii, p. 641, April 28, 1894. Some new articles have been added to the present edition, some of the original papers have been amended, and a number have been rewritten. The new articles include modified milk and percentage milk mixtures and orthopedics. Those rewritten are typhoid fever, rubella, chicken pox, tuberculosis, meningitis, hydrocephalus and scurvy, while extensive revision has been made in the chapters on infant feeding, measles, diphtheria and cretinism. The volume has therefore been increased in size by about fifty pages.

The editor records with regret the decease of two of his collaborators who wrote articles in the previous volume, and which have been continued in this—Drs. Charles Warrington Earle of Chicago, and J. Lewis Smith of New York.

In most respects, the work is quite up to date, but we notice that the old weights and measures continue to be used in the formulæ, to the exclusion of the decimal system. So progressive a book should not be "behind the procession" in this respect.

A Clinical Text Book of Medical Diagnosis for Physicians and Students, Based on the Most Recent Methods of Examination. By OSWALD VIERORDT, M.D., Professor of Medicine of the University of Heidelberg. Authorized translation, with additions by Francis H. Stewart, A.M., M.D. Fourth American Edition from the Fifth German. Revised and enlarged. 194 illustrations. Pp. 603. Philadelphia: W. B. Saunders. 1898. Price, cloth, $4 net; sheep or half morocco, $5.

This favorite work needs no syndicate of professors to insure its sale at medical colleges. Although less than nine years elapsed between the date of the first edition and the date of the fifth, from which the present translation is made, the book has been kept carefully abreast of the progress of the times. The author himself has carefully revised his work four times. With the exception of the entire omission of the Roentgen ray, all the latest methods of diagnosis have been incorporated in this volume. This has been done purposely, as its distinguished author states that for purposes of internal medicine the application of the Roentgen ray is still in the beginning. It is quite possible that before another edition shall have been issued, its place in internal medicine will be more definitely fixed. In the meantime, this work remains, as before, one of the most valuable books of its class.

Transactions of the American Surgical Association. Volume xvi. Edited by DE FORREST WILLARD, A.M., M.D., Ph.D., Recorder of the Association. Pp. 319. Printed for the Association. Philadelphia, 1898. For sale by William J. Dornan.

The contents of this volume include the list of the officers, presidents, fellows and honorary fellows of the Association, the constitution and by laws, an account of the D. Hayes Agnew Memorial Wing of the University Hospital at Philadelphia, the address of welcome by Dr. Joseph Holt of New Orleans, the address of the President, and papers as follow: "Etiology and Classification of Cystitis," by N. Senn, M.D.; "The Question of Operative Interference in Recent Simple Fractures of the Patella," by Charles A. Powers, M.D.; "The Use of Animal Toxins in the Treatment of Inoperable Malignant Tumors," by George Ryerson Fowler, M.D.; "A Clinical and Histologic Study of Certain Adenocarcinomata of the Breast, with a Brief Consideration of the Supraclavicular Operation and the Results of Operations for Cancer of the Breast, from 1889 to 1898, at the Johns Hopkins Hospital," by William S. Halsted, M.D.; "An Inquiry into the Etiology of Cancer, with some Reference to the Latest Investigations of the Italian Pathologists," by Roswell Park, M.D.; "Remedial Measures in Obstruction of the Common Bile duct," by J. McFadden Gaston, M.D.; "Traumatic Rupture of Pancreas, Formation of Hemorrhagic Cyst; Operation; Pancreatic Fistula; Recovery," by H. W. Cushing, M.D.; "The Cranial Cracked-pot Sound as a Symptom of Cerebellar Tumors," by N. B. Carson, M.D.; "A Case of Appendicitis in which the Appendix became Permanently Soldered to the Bladder, like a third Ureter, Producing a Urinary Fecal Fistula," by W W Keen, M D , "A Case of Fecal Communication with the Bladder, with Resulting Calculus Following Appendicitis," by George Ryerson Fowler, M D , "Gunshot Injuries of the Spine," by T F Prewitt, M D, "Hysteria from a Surgical Standpoint," by James E Moore, M D , "Hypertrophy of the Prostate Gland, and Suggestions in Regard to its Treatment," by L C Lane, M D , "Some Cases not Operable," by David W Cheever, M D , "A Case of Apparently Hopeless Infiltration of Left Axilla and Scapula by Round celled Sarcoma, Extirpation Attempted and Abandoned, Extensive and Severe Wound Infection Followed by Disappearance of the Tumor," by Maurice H Richardson, M D

In this volume will be found a valuable paper on the etiology and classification of cystitis and a paper on fractures of the patella The surgeon who owns a complete set of the transactions of the American Surgical Association will have at his disposal one of the best exponents of American surgery that can be found in our literature, and he will have occasion to observe that the topics and discussions each year usually contain information in advance of the text books

A Text Book of Materia Medica, Therapeutics and Pharmacology —By George Frank Butler, Ph G , M D , etc Second edition, revised Pp 860 Philadelphia W B Saunders, 1898 Price, cloth, $4 net, sheep or half morocco, $5

In our first notice of this book, in Vol xxvii, p 1117, Nov 21, 1896, we expressed the opinion that it had certain features that would make it very popular—such as designating the precise orthoepy of all the names according to the Romanesque pronunciation, the use of the decimal system throughout, and having conveniently placed the genitive form after each official name These features are bound to be of use to students, and we are not surprised that the second edition was called for so quickly The work has been thoroughly revised, and, as we said before, "taken as a whole the book may fairly be considered as one of the most satisfactory of any single volume work on materia medica on the market"

Report of the Twelfth Annual Meeting of the Association of the Executive Health Officers of Ontario Paper Pp 72 Toronto Warwick Bros & Rutter 1897

This report contains the proceedings of the meeting held at Toronto, Ont , Aug 16 and 17, 1897 It is well printed on good paper, and contains much of interest to the physician

Transactions of the Medical Society of the State of New York 1898 Cloth Pp 512 Published by the Society, 1898

This volume contains proceedings of the Annual Meeting of the Society held at Albany in January of this year, with data as to delegates, permanent and honorary members, forty four papers presented at the Society, besides obituary notices of various deceased members of the Society, and a list of the officers of the Society from its organization up to the present time

Transactions of the Sixty fifth Annual Session of the Medical Society of the State of Tennessee Cloth Pp 300 Nashville Jno Rundle & Son, 1898

This volume comprises the minutes of the session held at Jackson, Tenn , April 12, 13 and 14, 1898, a list of the delegates to the American Medical Association, committees, judicial council, By laws, "Code of Ethics," and the various papers presented before the Society, with the discussions thereon

SOCIETY NEWS

Idaho State Medical Society —The sixth annual meeting of the Society was held at Moscow, September 6 and 7 The following officers were elected for the ensuing year President, C W Shaff, Lewiston , vice president, E F Guyon, Montpelier , secretary, Edward E Maxey, Caldwell The next annual meeting will be held at Lewiston, Sept 5 and 6, 1899

Mississippi Valley Medical Association —The annual meeting of the Association will be held in Nashville, Tenn , October 11, 12, 13 and 14 The provisional program contains seventy five papers and the members of the Association look forward to an interesting meeting Communications concerning papers should be sent to Dr Henry E Tuley, Louisville

The Thirteenth International Congress of Medicine —This Congress will meet in Paris, France, Aug 2–8, 1900 The section of psychiatry is already organized, with a committee of twenty-five of the best known alienists of Paris and the provinces, among them Bourneville, Professor Mairet, Paul Garnier, Meuriot, Falret, Vallon and Jules Voisin Dr Magnan is president of the section, Professors Joffroy and Ballet vice presidents and Ant Ritti of the Maison Nationale of Charenton secretary The subjects selected are In mental pathology, "The Psychoses of Puberty" , in pathologic anatomy, "Idiotism" , in therapeutics, "Bed Treatment in Acute forms of Insanity and the Modifications it may Entail in the Organization of Asylums" , in legal medicine, "Fixed and Impulsive Sexual Perversions from a Medico Legal Point of View " There are to be three addresses on each subject, one by a French "rapporteur" and two by foreigners

American Academy of Railway Surgeons —From the preliminary program of the fifth annual meeting, to be held at the rooms of the Chicago Medical Society, Chicago, Oct 5, 6 and 7, 1898, we note that the executive sessions are open to Fellows only In the scientific sessions, open to all those interested, the following papers are announced "Anesthesia," R H Cowan, Radford, Va , "Traumatic Injuries of Peripheral Nerves," D S Fairchild, Clinton, Iowa , "Injuries of the Genital Organs," Milton Jay, Chicago , "The Radical Cure of Hernia," W J Mayo, Rochester, Minn , "Concealed Meningeal Hemorrhage," H Reineking, Sheboygan, Wis , "Physical Examination for Railway Surgeons," J F Pritchard, Manitowoc, Wis , "The Hygiene of Railway Injuries," G P Conn, Concord, N H , "Conservatism in Railway Surgery," H Hatch, Quincy, Ill , President's Address, "The Higher the Order of Railway Surgery the Greater the Protection to the Employe, the Passenger and the Company," R Harvey Reed, Rock Springs, Wyo , "Convenient First Dressing of Fractures with Samples," E H Trickler, Cutler, Ohio , "Surgical T[illegible] of So[illegible] ties of Disease of the Prostate and [illegible] Benninghoff, Bradford, Pa The [illegible]

Academy have promised papers A D Bevan, Chicago, Allen Staples, Dubuque, Iowa, LeRoy Dibble, Kansas City, Mo, C K Cole, Helena, Mont, George W Crile, Cleveland, Ohio R Harvey Reed, M D, President, Rock Springs, Wyo, D C Bryant, M D, Secretary, Omaha, Neb

Virginia Medical Society—The annual meeting of the Virginia Medical Society was of more than usual interest It was held August 30 and 31 and September 1, at the famous watering place, Virginia Beach This is eighteen miles southeast of Norfolk, Va, on the Atlantic coast, and is one of those rare, wide, sand floor beachs so much enjoyed on the coast The Princess Anne Hotel was the home and place of meeting, and was an ideal spot for comfort and great pleasure It was a new feature to see crowds of medical men and their families disporting themselves in the surf night and morning, filling the air with joyous shouts and displaying all the enthusiasm of youth over again It was a delightful change from the dreary reading of papers to plunge into the surf and feel the force of the Atlantic waves with all their cool freshness If medical societies could meet on ocean shores in hot weather, both the science and the pleasure would be intensified in many ways The meeting was very largely attended, thirty six papers and two addresses were down on the program, all of which was carried out most carefully The president's address, by Dr Harvie, was replete with practical advice to the young men of the profession, and the public address by Dr Jones of Roanoke was interesting The first session was devoted to papers and discussions on diphtheria and the influence of bacteria in disease, and was spirited in its scientific and free expressions of opinions Dr Bolton of Brattleboro, Vt, described the bacteria of typhoid fever and its vitality and transmissibility under different circumstances All the papers were short and clear The second session was devoted to surgical papers Dr Phelps of New York gave a clinical paper on "Hip Joint Disease," and Dr Mallet of the University of Virginia gave some very interesting results of experiments on kreatin and kreatinin At the night session, many gynecologic questions in several papers of ability were presented at some length Papers covering a great variety of topics were read at the remaining sessions, some of which were followed by able and instructive discussion The meeting closed with a very pleasant banquet at the Princess Anne The publication of the papers at an early date indicates a very healthy spirit in the Society, which, while comparatively young in organization is fully equal to many of the larger and more pretentious societies Most of the members are widely scattered over the mountain and valley towns of the State, more or less difficult of access and isolated from each other, and yet in papers and discussion they show a familiarity with medical science that would compare favorably with that shown by city societies One thing noticeable is that the Virginia doctor can always express himself clearly in public debate He may not be well informed on all matters, but what he does know he can put clearly and smoothly in offhand talks The papers at this meeting were very common sense, and clear, unpretentious discussions of the most practical side of the topic Most of the physicians were educated in their own State at the very excellent University of Virginia and the Richmond schools, and a large number have received a classic training before their degree, hence a wider culture is apparent While the cross roads doctor and the irregular exist, they are hardly noticeable The Virginia medical man ranks higher socially than in other States, and this requires general culture and participation in the affairs of the neighbor hood calling for judgment on matters outside of medicine The examining board for admission to practice in the State has a very high standard of requirements, and many persons are rejected at every session The board has manifested a very strong determination to raise the standard of the profession throughout the State The State Society is greatly indebted to Dr Edwards, the secretary, who for years has worked incessantly to gather all the physicians in the State into a popular, enthusiastic society As nearly all the physicians are general practitioners, doing all sorts of general and special practice, the annual meeting is a postgraduate school to some degree, and each paper is listened to with much interest Noted specialists find in this Society very appreciative hearers and much pleasure in reading papers before them The Princess Anne Hotel management made the visit of the Society very pleasant in every possible way, and the Old Dominion Steamship Company from New York made it very pleasant for the visitors from the North The Virginia Society has found it practicable to hold their annual meetings at some watering place in the mountains or by the seashore during the hot season, and this example could be followed with advantage by other societies This would give greater attractiveness to the meetings and bring out larger numbers of the profession

NECROLOGY

William Lindsley Mussey, M D, Miami Medical College, Cincinnati, O, 1887, died in France, September 8 He was a son of the late Dr William H Mussey, and grandson of the late Dr Harvey Lindsley of Washington, D C He was identified with the Women's Medical College of Cincinnati, as Demonstrator of Anatomy and Professor of Dermatology and Syphilography He was also an Assistant Surgeon of the Children's Hospital of Cincinnati

Charles Carter, M D of Blowing Rock, Watauga County, N C, September 9 He was graduated from the College of Physicians and Surgeons in 1861, and in October of that year became an Assistant Surgeon, U S Navy Having served as such until February, 1863, he was appointed, after an interval of a few months, Surgeon of the U S Hospital, Turner's Lane, Philadelphia

Eugene S Forman, M D, University of Buffalo, N Y, 1870, died from apoplexy, September 13, at his home in Auburn, N Y

Joseph F Kuhn, M D, Long Island College Hospital, 1887, died at his home in Brooklyn, N Y, September 12, aged 34 years He was the son of Dr Louis DeB Kuhn

George S Hanna, M D of Hedgesville, Md, September 8, aged 70 ——Abbie G Hall, M D of Champaign, Ill, September 11 ——Louis Hess, M D of Brooklyn, N Y, September 11 ——J E H Nichols, M D of New York, September 10 ——A A Sylvester, M D of Columbia, Ga, September 11, aged 64 ——E Steifel, M D of Gallion, O, September 3 ——H Scarboro, M D of Ellaville, Ga, September 8, aged 86 ——Joseph O Wilcox, M D of Dresden, N C September 8 ——Stephen D Ayers, M D of Marion, Ind, September 15 He was born at Morristown, N J in 1811 ——Francis Huebler, M D of Elysburg, Wis, September 9

MISCELLANY

Personal—Prof Nicholas Senn has resigned his position of Lieut Col U S V, to resume his practice in Chicago

R Stansbury Sutton, Major U S Vols, has resigned, and resumed practice in Pitsburgh

A C Corr, M D, of Carlinville, Ill, has been elected president of the Illinois State Board of Health, vice A Adelsberger resigned

Congenital Lacerations—Congenital lacerations in the cervix uteri have been observed by Heil in three cases of nulliparæ, showing that the usual assumption that they are invariably caused by previous child bearing is not correct—*Cbl f Gyn* 1898, 19

Civil Service Change—The Medical Examining Board of the Chicago Civil Service Commission has been abolished by the Commission on the ground of economy The retiring examiners deserve the thanks of the community for the able and efficient manner in which they have performed their duty, but there is no valid reason why the City Health Department should not be utilized in this capacity

Diagnostic Value of the Reflexes in Lesions of the Cervical Portion of the Cord—Mendelssohn of St Petersburg, asserts that all normal reflexes pass through the superior portion of the spinal cord and the inferior portion of the medulla oblongata This theory explains the abolition of the reflexes with lesions of the cervical portion of the cord, as the lesion is an obstacle to their passage —*Bull de l'Acad de Méd* , May 10

The Tibia Substituted by the Fibula—Three years ago Poirier resected the whole of the shaft of the tibia on a boy for osteomyelitis, replacing it in two steps by grafting the body of the fibula on the two tibial epiphyses Radiographs now show that the graft has finely replaced the missing tibia It has grown from 4 to 20 millimeters in diameter and also increased in length, answering its purpose so well that the lad recently won the first prize for gymnastics at his school Another demonstration of the fact that the "function creates the organ "—*Semaine Méd* , May 25

To Improve Medical Certification in France—Last year there were published reports from the civil tribunal of the Seine to the effect that the judgment of the court had been that all medical certificates must be written from the personal knowledge and not from hearsay information of the physician making the report This year the court has rendered a judgment in a case which makes it a misdemeanor for a physician to certify to a lesion which would incapacitate the injured person from any labor for a considerable length of time, when in reality the injury was slight And if, in consequence of such a false certificate, an insurance company has paid an indemnity to the third person, the physician is liable for damages if sued by the company —*N Y Med Journ*

A Long Lived English Family—Dr C J B Williams of London, in proposing the health of Mr H Perigal, the treasurer of the Royal Meteorological Society, who was entertained at dinner on attaining his 92d birthday, gave some interesting particulars of the longevity of the Perigal family It appears they have been remarkable for longevity Mr Perigal's father, who was 99¼ years of age when he died, was one of thirteen children, nine of whom attained respectively their 64th, 67th, 77th, 80th, 88th, 90th, 94th, 97th, and 100th year, the last five averaging 93 years and 100 hundred days A brother of the treasurer, Mr Frederick Perigal, now in his 85th year was present at the dinner

Removal of Fibroma of Base of Skull—In order to open up the field of operation more completely, other methods having failed to accomplish the entire extirpation of the neoplasm, Max Jordan has operated two cases by lifting a tongue shaped flap, which included the entire nose and cheek nearly to the ear, resecting the upper jaw bone In one case he opened the flap down to the center, turning each half back, in the other, he avoided the central incision and turned the whole flap back from the ear In threatening cases and recurring growths, he advises this method in spite of the resulting scar, which shows only on the cheek, and is not very disfiguring, as can be seen from the cuts accompanying this article in the *Münch Med Woch* of May 24

Tinea Tonsurans in an Adult—Tinea tonsurans in an adult is an event of great rarity At a recent meeting of the Dermatological Society of London, Dr Aldersmith presented a man, aged 23 years, who had contracted the disease from a hair brush used by a younger brother who had ringworm There was only one patch and the majority of the hairs grew healthily and firmly, but scattered here and there were numerous black dots and very short stumps, some of which were in the form of little corkscrews The skin of the patch was smooth Such a case would probably have been overlooked without a careful examination with a lens The stumps were so fragile that one could not be extracted entire They were saturated with a large spore form of fungus—trichophyton megalosporon endothrix The modified manner in which the fungus grew in this case as compared with the tinea tonsurans of children is interesting, the unfavorable nature of the soil being evident —London *Lancet*

Lupus Treated with the Roentgen Ray and Hot Air—E Schiff reports two children with lupus completely cured to date by the application of the Roentgen ray, and Lang has also had similar success with the Hollander apparatus, a coiled metal tube connected with a Bunsen burner, from which a stream of hot air at a temperature of 228 degrees C at a meter's distance was directed upon the patches The scab and blisters formed were only superficial, and the resulting cicatrization proved much smoother and more esthetic than after any other process —*Münch Med Woch*

Sanitary Precautions Against Phosphorus Poisoning—It appears that the use of white phosphorus in match making is not interdicted in England, as it is in France and elsewhere An inquiry in the House of Commons on this subject led the Home Secretary to make a statement that speaks most favorably for the results which have followed sanitation in respect to the match industry He stated that the use of white phosphorus had been found less open to objection than has been asserted, on the contrary the information in his possession is that in some important countries, such as Germany, Austria and Belgium, its use is not prohibited In England the use of white phosphorus is regulated by special rules, which have been so far successful that last year only two cases of phosphorus poisoning occurred, neither of which was fatal In these circumstances he did not think there is sufficient cause for further legislative action —*Medical News*

Tetanus Cured with Intracerebral Injections of Antitoxin First Application to Man—The failures of antitoxin in curing tetanus are ascribed by Roux to the fact that the nerve cells have more affinity for the toxin than for the antitoxin, and they therefore take it up from the blood, leaving the latter to circulate ineffectually, unable to reach and neutralize the toxin then accumulated in the nerve cells The conclusion follows that the antitoxin must be introduced directly into the nerve cells to cure or prevent their intoxication, and this has been accomplished experimentally, arresting the disease at once and holding it stationary until convalescence commences A case of severe and progressive traumatic tetanus in a boy of 16 years, has thus been treated at the fifth day, pulse 120 to 130 The skull was trephined on each side with an 8 mm fraise, the dura mater incised and the needle inserted 5 or 6 centimeters at the base of the second frontal, far enough to avoid injury to the psychomotor centers, while still near enough to suffuse them with the antitoxin The tolerance of the intracerebral tissues was perfect, confirming the experimental work on rabbits and guinea pigs The disease was definitely arrested, although there was some subdelirium, insomnia, tachycardia and oliguria, probably due to the severity of the established infection Convalescence commenced the seventh day after the operation, complete nine days later —*Presse Méd* , June 18

The Danger of Contagion from Typhoid Fever in Hospitals—At a recent meeting of the Société Médicale des Hopitaux, of Paris, Dr Troisier stated that he had observed a case of typhoid fever in a young girl who was suffering from pleurisy, and that she had been surrounded by typhoid fever patients He stated, also, that the patient in question had taken nothing but a tisane, milk and Dhuys water Dr Netter recalled having observed in the Trousseau Hospital twenty seven similar cases, twelve of which had been among the atten [illegible] service Dr Gaillard had observed a case of typ [illegible] ich t patient had contracted while in the hosp [illegible] ardi had seen a similar case of contagion in a patient suffering from myelosyringosis In this case the pulmonary symptoms had predominated, and this had led him to the supposition that the contagion had been introduced by the respiratory tract —*N Y Medical Journal*

Medical Responsibility —Two cases have recently been tried abroad which have attracted much attention Professor Seidel of Brunswick was accused by his assistants of neglect of the ordinary precautions in operating, causing the death of a patient by infection from an unhealed furuncle on his finger The authorities informed him that an investigation would be made, which so distressed him that he committed suicide His brothers then brought suit against the assistants to restore their brother's reputation Bergmann cited on the stand the varying opinions in regard to gloves as an instance of the diversity of opinions that prevail in regard to asepsis, some considering gloves a progress, others a direct menace to the patient The Seidel brothers gained their case The other case was tried in France A woman was arrested suspected of infanticide, and Dr Méloche, who examined her twice, stated that there were probable evidences of a recent delivery, but a few days later the woman was delivered in prison of a living child Released at once, she sued the physician for 1000 francs damages, which were awarded her, the court adding to the peculiar features of the case by censuring him for not having examined the woman's blood A higher court has recently exonerated Dr Méloche and condemned the woman to the costs

The Maragliano Treatment of Tuberculosis —At Rome there has been opened an institute for the gratuitous supply of this serum to the poor Its chief promotor is Dr Passarini, who, on a tour of the Italian centers of population, where tuberculosis is most frequent, had his own convictions as to the efficacy of the serum confirmed by leading practitioners in those centers, and accordingly found the time ripe for such a dispensary in Rome as would place the prophylactic and curative virtues of the preparation within the reach of the humblest He, with a staff of assistants, will undertake the consulting practice of the Institute and be responsible for the diagnosis of the cases in which the serum is specially indicated, while Dr Maragliano volunteers the gratuitous supply of the serum in whatever quantities it may be called for The initiative thus taken is a noble one, and at the inaugural proceedings the large attendance of leading consultants, teachers and practitioners, attested the due appreciation of it on the part of the profession Its extension to other Italian cities can hardly fail to follow, and with the experience thus to be obtained, Dr Maragliano anticipates a still further advance on the lines he has worthily laid Nowhere more than among his compatriots has he found severer critics, but the rise of the new dispensary may be taken as significant that opposition has passed its acute stage, and that, to use Baccelli's words, the Maragliano serum has at length vindicated "its right to citizenship" in the medical commonwealth

Alcoholic Somnambulism —Dr Francotte of Liége has published a carefully prepared paper, having special reference to the medico legal relations of the somnambulism which is met with as a result of alcoholism Somnambulism, regarded as the condition in which during loss of consciousness co ordinated actions are carried out, of which there is no recollection afterward, is met with not only in hysteria, epilepsy, and the hypnotic state, but also as a result of alcoholic indulgence The author relates the following case of a man who was arrested for disorderly conduct in a public place He could not be induced to answer questions or even to speak, and appeared to be quite demented There was no sign of intoxication, but next morning at the medical examination, he confessed that at a place far distant from that at which he had been arrested, he had imbibed a large quantity of alcohol He had completely lost recollection of what had occurred during the next forty eight hours He confessed to other excesses in alcohol, and there was marked tremor of the hands and of the tongue A sister had been the subject of mental disease The author, after citing several examples, concludes that there is a species of alcoholic somnambulism in which the patient behaves to all appearance in a normal way, but without consciousness, or at least without having any recollection of what he has done In reality, however, during such a time, certain slight peculiarities of conduct are present which may easily escape the observer The condition manifests itself only in degenerate individuals, or at least in those who have inherited some psychic weakness, and as it is one which implies the absence of responsibility, unless it is intentionally induced, it is of great medico legal importance —*Neurologisches Centralblatt*

Benefactions made by Women —It is not often that two so large bequests by women come to the knowledge of the public at about one and the same time as are those lately made by two women of New York State Two colleges and a hospital benefited by the wills of two women who have recently died Mrs Annie S Paton of the borough of Manhattan, has bequeathed $100,000 to the Princeton University and $50,000 to the Manhattan Eye and Ear Hospital, and Dr Elizabeth Bates of Port Chester, has left $125,000 for the endowment of a chair in the medical department of the University of Michigan, for instruction of the diseases of women and children In addition to her direct bequests, Mrs Paton has left $100,000 more to Princeton and $50,000 more to the hospital contingent on the death of her children, who have a life interest in the sums named Dr Bates was a graduate in 1853 from the then young and struggling Philadelphia College for Women, at the time prior to her decease, Dr Bates was one of the school's senior surviving ex students and alumnæ These gifts bespeak our attention to the generosity of women to charitable objects and to education, although it is no doubt true that the major part of the benefactions to colleges and hospitals have come from men, this fact is readily explained by that other fact that the property is held in the name of the legal head of the family If the truth were known it would be found that many gifts have been suggested by the wife, and that frequently both husband and wife have united in planning for the benefit of the object of their mutual generosity

Hospitals

The management of the South Barnabas Hospital of Minneapolis, Minn, has issued a circular soliciting donations to be applied to the hospital debt of $25,000 The authorities are making strong efforts to raise this amount on account of the availability of $50,000, left by the late Richard Martin, depending upon the liquidation of the debt

The Ensworth Hospital, St Louis, Mo, has been purchased by the Methodist Episcopal Church, which will take charge of the institution October 1

At a recent meeting of the directors of the Mount Zion Hospital Association, San Francisco, Cal, it was decided to commence the erection of a new hospital, with accommodations for fifty patients, to cost about $40,000 This institution is a charity hospital, supported by Jewish subscriptions

The formal opening of the St Margaret Memorial Hospital, Lawrenceville, Pa, has been postponed from October 1 to November 15

The Employers' Hospital Association of East St Louis, has been incorporated with capital of $100,000

The Dunning (Ill) Hospital for Consumptives will be formally opened October 8 Arrangements are being made for the entertainment of those attending the inspection of the institution

The report of St Luke's Hospital, Jacksonville, Fla, shows that 112 patients were treated in that institution during the month of August

Bids for the Crozier Home for Inebriates, to be erected in Chester, Pa , have been opened The contract was awarded for $47,480

Detroit

Wayne County Medical Society —At the regular meeting of this society, held September 15, Dr E K Bacon read a paper on the subject of "The Anatomy and Physiology of the Sympathetic Nervous System and its Bearing on Pelvic, Abdominal and Mental Trouble " The Doctor gave an elaborate and exhaustive description of the anatomy of the sympathetic nervous system and traced its bewildering intricacies throughout the entire body, showing how organs remote are connected by nerve branches, and making intelligible the phenomena of associated clinical symptoms in parts of the body widely separated and apparently unconnected He enumerated a series of cases, occurring in his own practice, of reflex and sympathetic nervous irritation and explained clearly how, for example, dyspeptic symptoms are often caused from merely pelvic lesions, or how mental symptoms may be dependent upon abdominal pathologic conditions

The society discussed the advisability of amalgamating with the Detroit Medical and Library Association This society and the Wayne County Society are the two leading medical societies in the city, and many of the members of both societies have long desired a union of the two, but many difficulties have stood in the way, the chief one being in the choice of a name After some discussion the question was tabled

Dr A H Steinbrecher reported nineteen cases of fever among returned soldiers he was treating at Harper Hospital He stated that while many of the cases resemble typhoid fever, yet they are all undoubted cases of malarial fever Widal's serum test has failed in every case while in nearly all the plasmodium has been found in the blood

Health Report for the week ending September 17 Deaths 75—under 5 years 37 , births 72—male 31, female 41 , contagious diseases, diphtheria 7, scarlet fever 10 , deaths, from diphtheria 3, scarlet fever 6 One pair of twins born One case of smallpox

Louisville

Kentucky School of Medicine —The injunction granted Drs Kelley and Woody in the local courts, enjoining Dr Wathen from claiming to be Dean of the Kentucky School of Medicine, has just been made permanent by action of the Court of Appeals, it having been argued before that court and so decided

Surgical Society —The Surgical Society held its regular monthly meeting on the 5th inst , as guest of Dr Jas S Chenoweth A number of interesting reports of cases were made, and pathologic specimens exhibited Dr Chenoweth read a paper upon "Drainage of Cavities," and exhibited an ingenious apparatus for continuous drainage, specially applicable in gall bladder surgery A number of different appliances were shown for other uses of this apparatus, the most practical of which, perhaps, was that to be used in lavage of the stomach

MacCammon —Dr Vernon MacCammon has recently been appointed acting assistant surgeon in the United States Army and been ordered to Fernandina, Fla He is a yellow fever immune, and has traveled extensively in the tropics He is a recent graduate of the Kentucky School of Medicine

Louisville Society of Physicians and Surgeons —This society was entertained on the 8th inst by Dr Eugene C Roemele He read a paper entitled "Milk Infection "

Fowler —Dr and Mrs J W Fowler celebrated their silver wedding most pleasantly on the 10th inst Dr Fowler is president of the Kentucky State Board of Pharmacy, president of the Louisville College of Pharmacy, and member of the State Pharmacy Examining Board About two hundred guests were present on this most delightful occasion, and received invitations from Dr Fowler to his golden wedding, twenty five years hence

San Francisco

San Francisco County Medical Society —Dr McCone presented a case of syphilis of the peritoneum, at the regular meeting of this Society for the month of September The history of the case was about as follows A woman presented herself at the University of California clinic, some time in May, saying that the trouble for which she sought relief had existed for the past eleven months, steadily growing more aggravated She was a prostitute, 29 years old, had two children, no miscarriages, and had been previously regular in her menstrual law She acknowledged to the initial sore of syphilis, four years previously acquired, but said that she had had no trouble that could be, in her opinion, due to that cause On examination, the abdomen was found to be very much enlarged, with the umbilicus protruding , the genitalia presented a very curious condition There was a diverticulum connecting the vagina with the rectum , the anterior wall of the vagina and the bladder were drawn upward , all the parts in the neighborhood were very much injected and edematous A sound was introduced into the uterus and easily passed to a distance of five inches The mass in the abdomen exerted a mechanical pressure upon the lungs and heart which had very much interfered with respiration and the circulation She was sent to the City and County Hospital, where a consultation was held between Drs McCone, Kerr and von Hoffman , no diagnosis was made at this time, but it was decided to operate and see what the condition in the abdomen could be Dr von Hoffman operated, with the assistance of Dr McCone When the abdominal wall was cut through, there escaped 2½ gallons of a dark brown, coffee colored, apparently non purulent fluid The intestines were found somewhat matted together, and the whole abdominal viscera covered with a thin, delicate membrane A large number of nodules were observed in different parts of the abdomen Nothing at all characteristic of any known disease could be found, and the diagnosis was not made even at this time The patient did not recover from the operation, but rapidly sank and in a few hours died Postmortem examination showed a very great number of nodular enlargements in the abdomen, scattered promiscuously about, but nothing at all definite The nodules were red and were not broken down , some of them exhibited a very clear picture of granulation tissue , one was noted about the size of a man's fist, solid and not at all broken down Specimens were taken which were subsequently cut and examined microscopically, but with no new light being thrown upon the disease It was stated by one examiner of the specimens, that the disease might have been syphilis A more careful examination of the body after death, resulted in the discovery of some of the typic syphilitic scars, with round, punctured edges and thin skin, on the inner side of both thighs A careful search of the published literature which might possibly have any bearing on the case was made, with the result that it was found to almost parallel the case reported by Lancereau in his work The similarity between the two cases being so great it was assumed that the diagnosis of the case under discussion was in all probability syphilis of the peritoneum In reply to a question Dr McCone stated that the patient had had no abnormal temperature while she had been under observation either before or after operation The pathology of the case was discussed by Dr Douglas Montgomery and by Philip King Brown, the latter holding opinion that while the disease might have been caused by, and might have been indeed syphilis of the peritoneum, there was absolutely nothing in the report of the case that would make such a diagnosis unquestionable He was also of the opinion that it would be absolutely impossible to make a diagnosis from the microscopic appearance of the specimens which had been removed, as they showed nothing except that there were nodules, in the abdomen, of granulation tissue, and that these were not broken down, as one would expect to be the case in tubercular peritonitis The presence of the sero purulent membrane rather contraindicated syphilis as the causative factor

Dr F Dudley Tait agreed with Dr Brown in his opinion that the diagnosis of syphilitic disease of the peritoneum had not been shown in the case reported, and the condition may have been something quite different He was also of the opinion that it would be absolutely impossible to diagnose syphilis by means of the microscope The case may have been one of tubercular infection, or infectious inflammation from some other cause, it might also have been due to syphilis, but this was far from having been proved to be the case Dr McNutt exhibited the kidneys of a man of about sixty who had been killed by a passing car, while jumping from the cable car on which he had been a passenger There had been no history of any disease of the kidneys and the man was considered to have been in perfect health up to the time of his death On postmortem examination the kidneys were found to measure 9 x 4 x 6 inches, and to weigh three pounds each, they were one mass of multilocular cysts, hardly any trace of true kidney tissue being discernable He read extracts from the most recent writers on the subject, the majority of whom were of the opinion that cystic disease of the kidney, of this variety, was a congenital affection which had persisted into adult years and was seldom the cause of death The specimens were exhibited and were particularly fine On motion of Dr Philip Mills Jones, the sum of $500 was voted for additions to the library

APROPOS of the discipline of the Tennessee regiment, a recent visitor to the Presidio, where the regiment is encamped, witnessed a number of the men tossing one of their officers in a blanket On inquiry it was discovered that the officer in question had done something to displease the men and they were simply adjusting the punishment to fit the crime

Two of the positions left vacant by the death of Dr J F Morse, have been filled Dr L Bozet has been appointed to the Board of Health, and Dr Fehlaisen has received the appointment as chief surgeon to the German Hospital

THE PUBLIC SERVICE

Movements of Army Medical Officers,—To duty with troops at Camp Wikoff Montauk Point L I Major Charles Adams, brigade surgeon, from Camp George H Thomas Ga Major Royce D Fry, brigade surgeon from the general hospital Ft McPherson Ga Major Eugene L Swift brigade surgeon from camp at Lithia Springs Ga, Majors Henry I Raymond and Adrian S Polhemus brigade surgeons from the 3d Corps at Chickamauga Park, Ga Major Chas M Gandy brigade surgeon from Tampa Fla and the following Acting Asst-Surgeons Herbert I Harris from Buffalo N Y Edward M Parker from Washington D C Thomas H Lowe from Baltimore Md Raphael A Edmonston from Washington D C Delos L Parker from Detroit Mich, James McV Mackall from New Haven Conn Elijah J Russell from Baltimore Md Charles A Hamilton and Wm O Cutliffe from Washington, D C Orrin S Mills from Gallipolis, Ohio, Frederick W R Lapsley from Chicago, Ill, John A Tanner and Henry B Lee from New York City, George Dock from Ann Arbor, Mich W T Hamilton and Stephen M Long from Washington, D C Charles H Fischer from Detroit Mich, and James S Kennedy from sick leave at Chambersburg Pa

To duty with troops at Camp Meade, Pa Major Frank Bruso brigade surgeon, from the 3d Corps at Chickamauga Park and acting Asst Surgeon Donald Maclean from Detroit Mich

To duty with troops at Lexington Ky Acting asst Surgeons Matthew Leepere from Milan Mo Henry J Hinkel from Baltimore Md Philip P Parrish from Afton, Va William J Boyd from Pavilion, N Y, and James B Stewart from Bradford, Pa

To duty with troops in Chickamauga Park, Ga Acting Asst Surgeons Howard Carey from Sand Beach Mich Erwin I Shores from Bridgewater, Mass, William T Tanner from Buffalo N Y F Arthur Zeller from St Paris, Ohio Charles S Pinckney from Charleston S C, Alfred O Stimpson from Thompson, Pa, and Josiah B Trudgian from Washington, D C

To the Sternberg hospital in Chickamauga Park, Ga First Lieut Jesse Roux, Asst Surgeon 1st Illinois Cavalry, and acting Asst Surgeon George Dock from duty at Montauk Point L I

ORIGINAL ARTICLES

IMMUNITY THE FUNDAMENTAL PRINCIPLE UNDERLYING ALL TREATMENT OF TUBERCULOSIS

Presented to the Section on Materia Medica Pharmacy and Therapeutics, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June, 7 10 1898

BY LAWRENCE FLICK, M D
PHILADELPHIA, PA

The principles underlying the treatment of disease have in the past been matters of speculation only What was known to do good had been found to do so empirically, and was handed down from one generation to another in the most dogmatic way With the birth of the germ theory of disease speculation gave way to exact science, and it became possible to base plans of treatment upon rational theories In the light of the germ theory of disease, immunity becomes *the fundamental principle underlying all treatment* of those diseases which are due to living organisms The usefulness of a plan of treatment must therefore be predicated upon what it will contribute toward maintaining or bringing about immunity

Certain axioms can be formulated out of our present clinical and laboratory knowledge of germ diseases These are 1 That all germ diseases are due to parasitic life of living organisms 2 That there is in all living organisms an inherent power of protection against parasitic life 3 That the power inherent in the human organism protective against disease is potent in direct ratio with normal physical development and normal standard of health 4 That a proper soil for a given disease germ must exist in a prospective host as a pre-requisite for the establishment of the disease 5 That the soil necessary for the subsistence and development of any given disease germ in a host may become exhausted 6 That the normal physical development and normal standard of health with the consequent relative resisting power to disease, are closely related to nutrition in the individual, and in the ancestry from which the individual has sprung 7 That congenial soil for a disease and inherent resisting power to it, may both exist in their fullest intensity in the same individual at the same time

Of no germ disease have we, probably, as exact and intimate a knowledge as of tuberculosis We can therefore lay down the following additional axioms about it as a basis of treatment 1 That tuberculosis is essentially a local disease, and as such is slow in exhausting the soil in the host in whom it colonizes 2 That tuberculosis, as a disease in its complete symptom-complex, is a series of colonizations, each colonization, in the complete cycle of its existence, constituting a minor attack 3 That each colonization which runs its course, leaves the system of the host less competent to battle against a subsequent attack 4 That every successive colonization is more extensive and more devastating than the preceding one 5 That when a colony has been established, cure can only take place either through phagocytic powers of the blood by destruction of the bacilli before the circulation has been cut off from the deposit, or through defensive powers of the system by necrosis and ejectment of the mature bacilli, or by encapsulation 6 That during the process of necrosis and ejectment of the mature bacilli re-inoculation may take place

Upon the general and special axioms here laid down, the scientific treatment of tuberculosis must be based, and the fundamental principle that grows out of them is that immunity must constitute the basis of all treatment

Immunity to disease is a freedom from liability to disease, because of an innate or acquired condition of the system, which is inimical to the development of the disease In other words, *it is an uncongenial soil* for the germs which produce the disease For the proper understanding of what is meant by immunity, it is first necessary to get a clear conception of what constitutes soil Soil is a complex condition having both a positive and negative qualification It may be a condition of the system in which disease germs find something in the blood or tissues upon which they can luxuriantly feed and prosper, or it may be a condition of the system, in which there is lacking something in the blood or tissues, which if it were present the germs could not obtain a foothold Immunity being conditioned upon soil is therefore of a two-fold nature 1, natural immunity, and 2, artificial immunity Natural immunity is that condition of the system in which there is something present in the blood or tissues which inhibits the colonization of disease germs, in other words, it is the innate resisting power to disease Artificial immunity is that condition of the system in which the specific pabulum for the disease germs has been taken out of the blood or tissues, either by a prolonged resistance to implantation of the germs, or by a successful struggle through an actual colonization of them Immunity is not a fixed absolute condition, but varies from a slight temporary resisting power to an absolute permanent impediment to disease

While tuberculosis subscribes to the general laws which govern germ diseases, it differs somewhat from most germ diseases in the matter of immunity With such diseases as smallpox, scarlet fever and measles, natural immunity is weak, and a single attack of the disease is likely to establish absolute and permanent artificial immunity with tuberculosis natural immunity is strong, but artificial immunity is exceedingly difficult to establish Natural [illegible] fr[illegible] tuberculosis is, however, not [illegible] and peoples, nor even by all f[illegible] not been exposed to the disease, such as the colored race in the interior of Africa at the present day, and the native races of America before its settlement by Europeans, do not possess it at all, country people possess it in lesser degree than city people, and some families are absolutely devoid of it This difference may be explicable upon the theory that strong natural immunity really may be artificial immunity gradually acquired through long exposure to the disease by races, peoples or special families As a rule natural immunity from tuberculosis goes hand in hand with normal physical development and a normal condition of health, and this is true to a much greater degree of tuberculosis than of most germ diseases Complete artificial immunity is very seldom attained, although a very high degree of artificial immunity may be reached by certain families Artificial immunity in the individual is sometimes acquired in bone tuberculosis and possibly also in glandular tuberculosis The reason why complete artificial immunity is so seldom attained is, because when the disease is once established, the natural immunity or resisting power of the person affected gradually gives way and becomes exhausted before artificial immunity can be established That there is, however, a tendency in every case of tuberculosis toward the establishment of artificial immunity can not be doubted, for we have evidence of it not only in the gradually increasing chronicity of the disease, but in the degeneracy of the tubercle bacilli as the disease advances Could the natural immunity of the individual be maintained at a normal standard, a very large number of cases would undoubtedly recover as artificial immunity would ultimately be acquired and the germs would no longer find congenial soil for the establishment of new colonies There are really very few cases of tuberculosis in which recovery does not take place from the first attack and in many cases complete restoration to health follows a second, a third, and even a fourth attack, but unfortunately after each attack there is lower physical tone—a lower natural immunity, and recovery is slower and less complete, with the chances of ultimate permanent recovery greatly diminished

In the treatment of tuberculosis the great and important object should be the maintenance of natural immunity and the establishment of artificial immunity Everything possible should be done to maintain the normal standard of health, first by preventing the waste of force, and secondly by stimulating the organs which have to do with nutrition To prevent the waste of force it is necessary to suspend all activity over and above that which is necessary for a normal circulation and the proper action of the emunctuaries Over-work among the poor, and over exercise among the well-to-do are serious impediments to recovery There is a popular idea, shared by too many physicians, that tuberculosis is due to inactivity of the lungs, and that the natural remedy is a great deal of out-door exercise The mischief caused by this erroneous idea is beyond calculation As well might one expect a typhoid fever patient to recover under a régime of hard labor, as a person suffering from tuberculosis while pursuing an active career Absolute rest is the proper treatment in all cases of tuberculosis so long as there is marked variation of temperature and excitability of circulation Not only will the resisting powers of the patient be conserved by such treatment, but the nutritive powers of the system will be greatly increased Loss of weight will cease, appetite will improve, digestion will grow better and the general condition of the patient will show marked improvement after a few weeks' rest in bed When the acute symptoms have subsided and the circulation approaches a normal condition, passive exercise may be taken with benefit Watchfulness should, however, be maintained, so that even passive exercise may be suspended the moment evidence of disturbed circulation reappears Not until the circulation becomes normal, and all evidence of activity of the disease has disappeared, should fatiguing exercise be permitted There is no rule of practice of greater importance to the welfare of the patient than this, for a single fatigue may be the turning point in the case from the road to recovery to the road to fatality

By advocating rest and partial inactivity during the convalescent stage I do not wish to be understood to favor indoor life or to oppose open-air treatment On the contrary, I deem it of the greatest importance that even in the most acute stage pure, fresh air be supplied to the patient night and day, and that the whole mode of life be regulated with this end in view There is nothing inconsistent, however, between the ideas of absolute rest and plenty of fresh air, for such rest can be secured even in the open air if necessary, and can always be had in well-ventilated rooms Sleeping-rooms should be kept well ventilated night and day and where they can not be properly heated the patient should be sufficiently protected by clothing to permit of thorough flushings at frequent intervals The ideal treatment for tuberculous subjects is really only attainable in sanatoria where everything can be so planned that patients may spend most of their time out of doors even in the acute stage of the disease, where the sleeping-rooms can be well ventilated, and where the physical exercise can be regulated to suit the requirements of each case In home treatment we must do the best we can, but with the two ideas of rest and plenty of air always in mind and as the basis of every plan of treatment and every act of life

Next in importance to preventing the waste of force, is stimulating the nutrition so as to make up for the ravages of the disease Tuberculosis being a parasitic disease, and one which usually attacks some important part of the machinery of the body concerned in nutrition, there is bound to be a loss in nutrition and a deterioration from the normal standard of health In proportion as this loss can be repaired will treatment of the disease be successful In this connection the close relationship and interdependence of the respiratory and digestive tracts in the function of nutrition and their common government by the pneumogastric nerve must be ever kept in mind As this nerve supplies both the lungs and the stomach, an embarrassment to the lungs is bound to prove an embarrassment to the stomach In treating tuberculosis of the lungs the most constant attention should therefore be given to the stomach, and every weakness and incapacity anticipated By reason of nervous inhibition and perverted nervous function growing out of the diseased condition of the lungs, appetite is often wanting, or a morbid craving for food, which, if taken, will prove injurious, exists Want of appetite and morbid cravings of food must therefore not be heeded, but a liberal and judicious feeding must be pursued An ample supply of easily digested food at frequent intervals will probably give the best results The largest amount of nutrition with the smallest amount of labor to the digestive tract should be the golden maxim by which every article of diet is judged Artificial aids to digestion, both in the stomach and in the intestines, can always be employed with advantage Great care should be exercised in giving drugs, such as alteratives and cough medicines, by the stomach, for the purpose of influencing the course of the disease The good that may be accomplished with such drugs is more than counterbalanced by the impediment to nutrition which they bring about and the consequent deterioration in natural immunity There are many drugs, such as strychnia, alcohol, cod-liver oil, hypophosphites, mercury, the mineral acids and the vegetable tonics, which may be used to advantage for maintaining natural immunity They should, however, all be used with care and only when indicated for a specific purpose Animal and vegetable ferments, such as pepsin, pancreatin and diastase are likewise most useful remedies for this purpose when judiciously used

In the matter of artificial immunity we seem to be at the dawn of a great day Much can already be accomplished with the methods and remedies at our command, but what we can do now is merely a foreshadowing of what is to come In the past, climate has been our chief resource as a means for the attainment of artificial immunity With a better knowledge of tuberculosis and more careful observations of the results of treatment, a change seems to be coming over medical opinion as to the value of climate as a therapeutic agent Personally I have long since abandoned the idea that there is any specific power in climate over tuberculosis That climate may contribute something to the maintenance of natural immunity I have no doubt, but as between the advantages to be derived from the best climate and those which accrue to the average patient in comfort and nutrition at home I believe the preponderance to be on the side of home Whatever advantage there may be in climate will only be attainable to the majority of persons suffering from tuberculosis when sanatoria have been established in appropriate places to which patients can either be admitted free or upon payment of nominal board

There has been much disappointment in the serum treatments They one and all aim to establish artificial immunity and thus to bring about a cure Personally I have had no experience with any of them and I am therefore not in a position to speak of them with authority I have, however, read all the literature upon the subject within my reach and have kept close watch upon reports of cases treated with animal immunizing agents of any kind I believe that all contain some merit, and in the hands of the proper persons are legitimate therapeutic agents I have not used them because of lack of intimate knowledge of them, and also in part because of diffidence inspired by conflicting reports about them That their genesis is upon correct principles, however, I am thoroughly convinced, and I look forward with great anticipation to the discovery of a specific remedy along the lines upon which they have been worked out

Of drugs that have the power of contributing to the establishment of artificial immunity we have at least two that are worthy of confidence These are iodin and creosote In my opinion iodin approaches nearest being a specific for tuberculosis of all agents now known That it is an absolute specific where it can be properly applied I am certain, but the great difficulty lies in the application I have for many years obtained the most decided results by daily inunctions with a solution of iodoform or europhen in oil The virtue of these drugs lies undoubtedly in the iodin, and the mode of action appears to be the production of nascent iodin in the blood by the decomposition of the iodoform and europhen, and a consequent inhibition of the tubercular process The treatment is successful in proportion to the incipiency of the disease and the integrity of the circulation throughout the deposit Of incipient cases that I have treated nearly all have recovered, and of advanced cases many have shown remarkable improvement and some have recovered The reason why incipient cases recover so much more readily than advanced cases is because after necrosis has begun in a tubercular deposit medication through the blood is no longer possible, and the only hope of recovery lies in the prevention of new deposits And here the importance of artificial immunity as a factor in the treatment of tuberculosis becomes evident In proportion as artificial immunity can be attained the chances of reinoculation grow less, and if absolute immunity can be established recovery is assured Iodin might possibly give this absolute immunity could a method be devised of keeping the blood thoroughly under its influence until all danger of reinoculation has passed

Creosote is undoubtedly also a most valuable immunizing agent in the treatment of tuberculosis, and stands a close second to iodin It must however, be used in very large doses to get the full effects of which it is capable A dosage of fifty drops of pure beechwood creosote three or four times a day ought to be reached This amount can easily be given if the dose is gradually increased and copious liquid vehicles, which in themselves are not prejudicial to the stomach, be used Hot water is probably the best vehicle in which it can be given, but milk is sometimes preferable When milk is used the drug should be given after meals, so as not to interfere with the appetite Wine, alcoholic beverages, and oils are objectionable vehicles, because they may prove embarrassing to the nutritive process and can not well be taken in large enough quantities to properly dilute the creosote With the special preparation of creosote I have very little experience

LIFE HISTORY OF BACILLUS TUBERCULOSIS IN ITS RELATIONS TO THE TREATMENT BY TUBERCULIN

Presented to the Section on Materia Medica Pharmacy and Therapeutics
at the Forty ninth Annual Meeting of the American Medical
Association held at Denver, Colo, July 7-10 1898

BY ROBERT REYBURN, A M, M D

PROFESSOR OF PHYSIOLOGY AND HYGIENE, MEDICAL DEPARTMENT
HOWARD UNIVERSITY
WASHINGTON D C

It is said by Hirsch that about one seventh of the mortality that exists among civilized men is due to tuberculosis in its various forms, and when we consider the dreadful mortality due to this group of diseases, there is rather a remarkable fact that confronts us in studying the life history of the tubercle bacillus, namely, that it is apparently, when compared with many other species of bacilli and bacteria, very much less virulent and deadly

Let us compare for a moment the tubercle bacillus with the Klebs-Loeffler bacillus of diphtheria The tubercle bacillus, it is true, can be inoculated on m and cut surfaces, but only with great difficulty and under exceptionally favorable conditions which aid in its development Even when it does develop under favorable conditions of soil and habitat, its powers of growth and multiplication are slow and feeble, when compared with many other pathogenic micro organisms Compare this tardy process with the furious onset and virulence of the Krebs-Loeffler bacillus in a case of malignant diphtheria, the ghastly rigor followed by the burning fever and the septic infection produced by the absorption into the system of the poisonous toxins elaborated by these bacilli As the case of diphtheria goes on the glands of the throat become swollen and often purple in color, showing the still greater contamination of the tissues, and as death approaches the blood loses its coagulability and in fact resembles greatly the disorganized blood found in the veins after death from snake bite Tuberculosis, on the other hand, is comparatively slow and insidious in its progress There is also a marked difference to be observed in the organs attacked by tuberculosis in children, as compared with the same disease in adults In the former, tuberculosis commences usually in the glandular system, and the caseous glands may infect the adjoining organs, lungs, etc , by direct infection, or may set up a condition of general miliary tuberculosis In adults, on the other hand, in an enormous preponderance of cases the disease tends to localize itself in the lungs, and the digestive system and the glands are much less frequently involved The infection caused by the bacillus tuberculosis in adults is, there can be no doubt, produced by these micro organisms lodging in the nasal cavities, pharynx, trachea or lungs In children the infection is more general and very often seems to enter by the intestinal tract

The comparatively slow development of tuberculosis is of great utility to the physician and enables him to adopt measures of prevention that in many other diseases would be quite ineffectual It is a proposition that scarcely admits of argument, that when the tendency to tuberculosis is hereditary, and more especially when it prevails among the relatives of both parties desiring to marry, such unions should, as far as it is possible to do so, be prevented, unfortunately, however, the advice of the physician is often never asked, and if asked is still oftener disregarded While it sometimes occurs that women who are suffering from pulmonary and other forms of tuberculosis do bring forth and suckle children who are apparently healthy, yet the best authorities condemn the practice, as likely to be dangerous to both mother and child In these cases it is advisable to at once secure the services of a healthy wet nurse If the pecuniary circumstances of the parents render this impracticable, then the infant should at once be placed upon the use of sterilized cow's milk, properly diluted and slightly sweetened If the quantity of casein in the cow's milk causes indigestion, the excess can be removed by coagulating with pepsin or pancreatin and filtering through a piece of lace net In regard to the various kinds of infant foods so largely used in this and other countries, in my opinion they are utter abominations, and their use is responsible for the deaths of thousands of children annually Mother's milk is the perfect type of food for young infants, therefore all our efforts should be directed, in feeding these children who can not obtain their natural nourishment, to giving them as close an imitation as possible The basis of all the so called "infants' foods" is starch, which is not found in mother's milk, and requires for its proper digestion an action and such an activity of the digestive function of the small intestines as is not often to be found in young infants

As has been before mentioned, the infection of tuberculosis in infants and young children, more often take place through the glandular system of the intestines than through the mucous surface covering the respiratory apparatus This fact emphasizes the importance of most carefully scrutinizing the milk supply and the cattle whence the milk is procured, in order that no tubercular infection may be incurred from that source I am inclined to look also with considerable mistrust on the common practice of feeding young infants with scraped raw beef, believing it to be possible thereby to infect young children with tuberculosis, not to mention the possibility of other parasitic diseases, as for example, trichinosis As the infant grows and develops into the child new sources of infection for the development of tuberculosis are found to exist in the glands, so abundantly to be found on the surface of the respiratory mucous membranes

The crypts and follicles of enlarged tonsils form a nidus and resting-place for the retention and development of tubercle bacilli, the same may be said of adenoid growths in the vault of the pharynx, and of a catarrhal condition of the mucous membranes of the throat or nasal passages, whether produced by the above mentioned or other causes This chronically inflamed condition of these mucous membranes (commonly called catarrh) I believe to be a powerful predisposing cause of pulmonary consumption Another reason why enlarged tonsils and other growths in the pharynx should always be removed, is that they in great measure prevent the proper development of the chest and lungs In all cases of chronic catarrh I believe it to be of the utmost importance to insist upon the habitual and thorough cleansing of the nasal and post-nasal cavities with antiseptic solutions If this is not done the secretions of the part become more or less putrid, the resisting power of the blood serum of the organs on which we depend for the destruction of these and other pathogenic micro-organisms become weakened or destroyed and the body is thus rendered an easy prey to whatever poisonous germ may be able to find entrance

As will be readily understood from the previous part of this paper, the preventive treatment of this dread disease is by far, I believe, the most important Cases of this disease are, however, ever present with us, and the momentous question then presents itself What are the principles of treatment that should guide the physician in the management of cases of tuberculosis? The best answer to be given to this, therefore, will probably be found by making another inquiry, viz How are cases of tuberculosis (more especially tuberculosis of the lungs or pulmonary consumption) spontaneously or by medical aid cured? That these cases are cured is proven by the universally admitted fact that a large proportion of cadavers of persons who have died from many different diseases of the respiratory organs have, on postmortem examination shown indubitable evidences of having at varied periods of their lives suffered from tuberculosis of the lungs Dr J Hughes Bennet, in his classic work, "Clinical Lectures on Medicine," says (p 680) that the spontaneous arrest of tubercle in its early stages occurs in the proportion of from one-third to one-half of all the individuals who die after the age of 40. The observations of Roget and Boudet, made at the Saltpetriere Hospital, in Paris, among the individuals who were generally above the age of 70, showed that from one-half to four fifths of such persons had recovered from tuberculosis. As the larger proportion of these cases never received any medical treatment for their tubercular disease of the lungs, it must be perfectly apparent that the fluids or tissues of the body must have the power to destroy and render inert these poisonous micro-organisms. Where does this power reside? Metchnikoff thought he had discovered the answer when he elaborated the doctrine of phagocytosis, or the destruction of bacteria and other micro-organisms by the leucocytes or white corpuscles of the blood. Nutall, Buchner, Nissen, Lubarsch, and in this country, T. Mitchell Pruden and many others, have shown conclusively, however, that the power of destroying the bacteria, etc., resides not in the leucocytes, but in the blood serum. This preservative power of the blood serum also explains why it is that the human body is able to resist the destructive action of the innumerable poisonous micro-organisms which continually surround us. They exist in every breath of air we draw, in the articles of food we consume, and in much of the water we drink. Uncounted myriads of them are to be found in the digestive apparatus of persons who seem to be in all respects perfectly healthy. Professor Buchner of Germany states the time usually required for one microbe or germ to become two, by the process of division, is fifteen minutes. At this rate it is computed that a single microbe would produce in twenty-four hours a million million million times the present human population of the earth. Professor Law, in a paper published recently in the *Pharmaceutical Era*, estimates that a single bacterium dividing and redividing would produce in forty-eight hours, if undisturbed, 281,500,000,000, which in bulk would fill a half-pint measure—all produced in two days from a germ measuring the 1/150,000 part of an inch. Pathologic bacilli are just as numerous where found, and divide as rapidly. Professor Bollinger states that a cubic centimeter (about one fourth a fluid dram) of phthisic sputum (from a case of pulmonary consumption) contains from 810,000 to 960,000 tubercle bacilli. In an ordinarily copious expectoration the consumptive patient deposits nearly a million bacilli into his cup, and in an ordinary day he throws thirty or forty millions of these micro-organisms into the world. Then, at a low estimate, 10,000 tuberculous patients now living in New York City daily expectorate some 300,000,000 tubercle bacilli.

There exists, however, two conditions which have a most powerful effect in increasing or diminishing the power of the blood serum to destroy these poisonous micro-organisms. The first of these here to be mentioned is the high or low conditon of the health of the individual at the time of receiving the infection. If the individual is in a high state of health, his blood serum is then capable of destroying an immense number of these pathogenic organisms, and he is thus rendered immune to the disease.

Let us apply, then, the lesson to be drawn from the above-mentioned facts to the principles to be observed in the treatment of tuberculosis. Patients with tuberculosis can be cured when seen in the early stages of the disease and when they can be placed under proper conditions of hygiene. We enjoin perfect cleanliness, we direct that they shall receive an abundance of easily assimilated and nourishing food, we send them away from the vitiated and impure air of the city to breathe the pure and reviving air of the country, we give them cod-liver oil, tonics, the preparations of iron, iodin and its compounds, beechwood tar creosote, with now and then a little codein or morphin to allay the cough and procure sleep. This is not a long list of remedies, and in it there is nothing new. One fact to be noticed is that all the remedies which the experience of ages has taught us to be useful in tuberculosis are reconstructive medicines which tend to build up the body and improve the health. The second condition which greatly influences the fatality of tuberculosis as well as that of every other infectious disease due to the presence of poisonous micro-organisms, is that the deadly effects produced depend upon the number of bacilli introduced into the body at the time of receiving the infection. Experiments upon animals with many varieties of poisonous bacilli show a very close analogy to the phenomena produced by other poisons such, for instance, as opium, etc. If the dose of the poisonous bacilli is large, the animal dies, if it is small, his blood serum may destroy this limited number and he may recover. How then can we diminish this number of these bacilli in the immediate vicinity of our patient and thus prevent him taking into his system a deadly dose of these poisonous germs? The answer presents itself at once. Send your patient immediately to the seashore or country, still better, if his means permit of it, send him to the great table-lands of our country west of the Mississippi, to New Mexico or to some parts of California. He will come back to you perhaps in a year or two so changed and improved in physical appearance that you will scarcely recognize him. Above all things never send your consumptive patient to a sanitarium or a health resort, for if you do you have sealed his fate.

A great deal can be done to prevent the further infection of your patient, by the scrupulous disinfection of the sputum and its prompt destruction. Paper boxes for receiving sputum can now be procured for a trifle, these with their contents should be burned daily, thus removing at least one source of contagion. Tubercle bacilli in abundance have been found in the dust of rooms occupied by tuberculous patients, so the room should be as thoroughly cleansed and disinfected after occupancy by consumptives, as after having been used by patients suffering from any of the so called contagious diseases.

It is needless to dwell upon the stupendous failure of the lymph from which so much was hoped when it was introduced to us by the illustrious Robert Koch. It is perhaps presumptuous in me to have an opinion on a matter that belongs so especially to those who have made bacteriology a special study, yet I can not help expressing a conviction that we can not expect as much benefit as we hoped we would receive from these investigations. It seems to me that such laborers are working in a wrong direction. Since the world began tuberculosis has always been cured in one way, namely, by improving the hygienic or general health, and how the injection into the system of a concentrated extract of the poisonous materials elaborated by the bacilli can do this I am unable to discover. I had the opportunity of studying the effects of the hypodermic injection of the lymph sent by Robert Koch to this country My limited experience of its use leads me to believe it a most energetic and poisonous fluid, and one that is much more likely to injure than to benefit patients who are suffering from tuberculosis Other observers have had also very unfavorable experience with the new Tuberculin R of Professor Koch, as will be seen from the following taken from the *Medical News*, March 19, 1898, p 378

> The last two meetings of the hospital staff of the Charité (which constitutes a sort of medical society with bi weekly meetings) have been occupied with a discussion of Koch's new tuberculin– tuberculin R In April it will be year since the authoritative publication of the new method and announcement of the remedy Some definite conclusions, it would seem, might be reasonably expected The drift of opinion was all against the tuberculin R , and most of the clinicians did not hesitate to compare it to the old tuberculin in its effects, and some of them in its possible dangers Dr Huber, an assistant in Professor Leyden's clinic, has attempted to immunize animals in the way in which Koch immunized the animals which served as the basis for his conclusions in his last communication, but utterly failed The experiments seem to have been carefully carried out, the dosage of tuberculin was exact and sufficient and the observations numerous enough to do away with the idea that perhaps coincidence played a rôle in the results obtained Yet he failed to get the desired immunity The full details of the experiments are to appear in the next number of the *Zeitschrift für klinische Medizin*, of which Professor von Leyden is the principal editor After supposed immunization all the animals died when inoculated with tuberculous material, and interestingly enough, most of them before the control animals inoculated with the same material at the same time
>
> In Professor Leyden's clinic there has been absolutely no success with the new tuberculin Patients acquire an immunity to reaction from the tuberculin itself, but no curative effects on tuberculin deposits have been noted At times some improvement occurred, but there never was complete disappearance of any physical signs of the disease which had been previously noted In patients with fever even Koch himself does not recommend it, and there is no doubt that it can and often does do harm in such cases
>
> Non tuberculous patients may react to even small doses of tuberculin R , so that the employment of any such reaction as a sign of the presence of a tuberculous process in a given case is said here to be utterly delusive The conclusion of the experience in the medical clinic is that it is not a specific Therapeutically it is no better than other forms of treatment which are not near so costly and not near so worrying to the doctor , for in no case can this treatment be employed except under a doctor's immediate supervision These conclusions are shared by the workers in Professors Gerhardt's and Senator's clinics
>
> Even Professor Frankel, the throat and nose specialist, who, on the strength of some lupus and laryngeal cases in which at first improvement seemed very rapid, was for some months an advocate of the new treatment, now admits that it is practically no better than many other forms of treatment for these affections, that it often fails to produce a change in the course of the disease, and never produces radical cure Only Professor Briger, Professor Koch's assistant in the Institue for Infectious Diseases, makes any claims as to the value of the tuberculin treatment The history of the second tuberculin forms an interesting commentary on the enthusiastic reception of the first Here it has had practically the effect of destroying faith in all so called specific remedies for tuberculosis Constitutional treatment, especially such as can be given in favorably situated, specially arranged consumption hospitals, is now the only method receiving any attention

Another and a very serious objection to the use of tuberculin R for diagnostic purposes arises from the fact that many people have encapsulated tubercular bacteria in the apices of their lungs, which are for the time being harmless If we inject the tuberculin R and obtain the reaction characteristic of tuberculosis we may awaken to activity these dormant germs and thus aid in poisoning the system of our patient instead of promoting a cure of his disease

While wishing most heartily, therefore, that the results of the injections of tuberculin R should have aided in destroying the most dreadful disease that afflicts humanity, yet we feel compelled to say that we have little hope of the cure of tuberculosis by this means

---

ANTISTREPTOCOCCIC SERUM

Presented to the Section on Materia Medica Pharmacy and Therapeutics
at the Forty ninth Annual Meeting of the American Medical
Association held at Denver Colo June 7-10 1898

BY WARREN B HILL, M D
PROFESSOR MATERIA MEDICA AND THERAPEUTICS MILWAUKEE MEDICAL COLLEGE
MILWAUKEE, WIS

Serum therapy has afforded a large field for speculation and exploration, and the achievements in it have marked an era in medicine The brilliant success of antidiphtheritic serum have assured us of the practicability of this mode of treatment in bacterial diseases, and we are justified in the hope that like results will be obtained in many or all diseases of this character It now remains for us to determine the bacteria which produce a given disease and provide a suitable medium for their cultivation, and the proper organisms for the production of antitoxins, and we may hope for a specific agent in the disease in question

The task here briefly laid out is by no means an easy one All diseases are not of bacterial origin Again the most virulent microbes do not always stand artificial cultivation without deterioration, and the tolerance or natural immunity in species or individual animals makes it no easy task to produce antitoxins of a given standard We are all cognizant of the work that is being done with the various antitoxins and are often surprised and disappointed because the results have not been so certain as in diphtheria Nevertheless, much has been accomplished, and the finer problems are being worked out one by one Advancement along this line is sure and certain, and the time is not far distant when other antitoxins will stand shoulder to shoulder with that of diphtheria and command the respect and attention of the medical profession for the results achieved To Marmorek is due the credit for the original work in antistreptococcic serum, but Dr Charles C McClintock of Detroit has carried on the work in this country so admirably that we have an American product which is as good as is possible under the existing conditions of our knowledge of this subject He, like other experimenters, has found it difficult to maintain pure cultures without deterioration This has been overcome in a large degree by inoculating rabbits and other susceptible animals with large quantities of pure culture, and in such rapid succession that a virulent culture is produced Having thus obtained a powerful toxin, a suitable animal must then be procured for inoculation This is somewhat of a difficult task, as in all of the domesticated animals there is the personal equation to be accounted for We all know that in man certain individuals are far more susceptible to streptococcic infection than are others This is also true of the horse The thoroughbred is not available, because of cellular degeneration due to inbreeding The animal dies, not because of his particular susceptibility, but because of the inability of the cells to produce a suitable antitoxin Again, the scrub is not available because of his tolerance, and a sufficient reaction does not take place to produce a standard antitoxin. Dr. McClintock was obliged, therefore, to select by experiments individual animals which had the power of producing a suitable serum. Recently he has carried on his experiments upon asses, and he believes them to be much more uniform in their susceptibility to streptococcic infection and capable of producing a more uniform antitoxin than the horse.

The animal selected is now inoculated with filtered cultures. Having thus obtained a slight immunity, he is next inoculated with pure cultures, the vitality of which have been impaired by heating. The virulence of the cultures is now gradually increased at each injection until he is able to withstand, with little or no reaction, large quantities of pure cultures of the most virulent type. This procedure occupies a period of time of from one to two years. The blood is drawn off and the serum is gathered and prepared in the same manner as for diphtheria antitoxin. Another difficulty now confronts us in the standardizing the antitoxin. This is usually accomplished by first determining the fatal dose of the toxin upon a given animal. Other animals of the same species are now injected with a great many times the fatal dose, and at the same time with a given quantity of the antitoxin. By continuing these experiments it can be determined to what extent a given quantity of the antitoxin will immunize the selected animals. Up to the present time this has not been accomplished because of the difference in susceptibility of different animals of a species to streptococcic infection. However, in a general way this has been accomplished, inasmuch as animals which have been inoculated with this toxin have died, while others of the same class and inoculated with large quantities of this toxin have been saved, or their lives prolonged, or their symptoms ameliorated by the use of antistreptococcic serum.

The practical work of this serum has not been confined to the laboratory. It has been largely used upon human beings, and while the results have not been uniformly good, there have been enough successes, and brilliant ones to commend it to the profession for their careful consideration and approval. Marmorek used it with great success in curing forty-five out of forty-six cases of erysipelas (*Therapeutic Gazette*, 1898, p. 114). Dr. Chantemasse has collected statistics respecting the treatment of erysipelas, both by the old symptomatic treatment and the new antistreptococcic, the mortality in the former was 3.79 and in the latter 2.59. Gauchez (*Therapeutic Gazette*, 1898, p. 1159) records the case of an infant six weeks old with erysipelas which started at the umbilicus and became general. After the usual line of treatment had been resorted to for fifteen days, the child gradually becoming worse, antistreptococcic serum was used, and after the first injection the temperature dropped two degrees. The child continued to improve and was cured.

A case of puerperal fever treated with antistreptococcic serum with happy results is reported in the *Lancet*, 1898, p. 779. Fraser notes a case of puerperal septicemia which was much modified after the injection of this serum (*Lancet*, 1898, p. 496). MacNalty (*British Medical Journal*, 1898, p. 85) records a successful cure of puerperal peritonitis with the serum. In the *British Medical Journal*, May 15, 1897, Watson Cheyne gives results of treatment of operation involving subsequent sepsis, where antistreptococcic serum was used with good results. He advises the injection after operation as a prophylactic against septic processes. A. Knyvett Gordon (*Lancet*, 1897, Vol. 1, p. 34) reports a case of rapid improvement due to its use in scarlet fever. In this case the child was to all appearances dying from septicemia; he was semi-comatose, with failing heart. After one injection he rallied, and after the second rapid improvement took place. Dr. A. W. Russell, at a meeting of the Glasgow Obstetrical Society held Feb. 24, 1897 (*Lancet*, 1897, Vol. 1, p. 813), reported a case of puerperal toxemia with symptoms of mania in which he had used antistreptococcic serum and recovery had followed. Dr. Guttman of Detroit had in his practice recently a case of general erysipelas which showed favorable results within a day after the injection of antistreptococcic serum. The fever and local inflammation at once began to decline and the patient was cured. The Doctor stated that he had exhausted every means known to him, but without any effect until he was advised to use the serum treatment. A case of acute otitis media cured with antistreptococcic serum is recorded in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Feb. 6, 1897, p. 272.

Reporting a case of septic absorption following the operation of oöphorectomy cured by the use of the serum, Dr. Scott McGregor (*British Medical Journal*, 1897, Vol. 2, p. 805) says: "I am inclined to believe that the recovery which resulted in this case, and with the small quantity of serum used, was due in a great measure to the prompt use of the serum at an early stage of the disease." Mr. Stephen Paget read a paper on cases of blood poisoning treated with antistreptococcic serum, and gave the general results of treatment up to the present time. He said that the four diseases in which the serum had received a fair trial were scarlet fever, puerperal fever, erysipelas and poisoned wounds. He presented statistics showing the great advance in reducing the usual frequency and fatality of the complications of scarlet fever, preventing suppuration, causing the throat inflammation to subside and in checking delirium.

My personal attention was attracted to serumtherapy as a cure for streptococcic infection some three years ago, when treating a case of inoperable sarcoma with Coley's toxins, when I completely immunized my patient against streptococcic infection. This demonstrated to me the feasibility of procuring an antistreptococcic serum, but having no laboratory of my own in which to produce the serum, I was obliged to wait until it was put on the market. At an early date I procured some made by Parke, Davis & Co. and commenced experimenting with it.

While thus engaged I was called to see a lady 71 years of age, of rather feeble constitution who was suffering from a violent attack of facial erysipelas, the infection having taken place in a small furnicle in the nose. The disease spread with frightful rapidity extending to both sides of the face, closing the eyes and involving the ears. The attack was so violent that one could see the invasion of new tissue. The temperature reached 104, pulse 140, the patient having all the symptoms of severe septic intoxication. I sterilized my field of injection between the shoulder blades and injected 10 c.c. of Parke, Davis & Co.'s antistreptococcic serum, which was all I had with me, and telegraphed them for more. This was at 2 P.M. In a few hours the patient be[illegible] the pulse became slower and the temp[illegible] degrees. At 4 A.M. the following [illegible]ed th nurse and told her she felt perfectly well The tenderness had entirely left the face, the toxic symptoms had subsided and the pulse and temperature were nearly normal At 8 P M the patient had a chill, which was followed by another exacerbation of the disease The heart was overpowered and showed signs of extreme intoxication The disease extended into the meatus of the ear, the temperature reached 103 5, which was followed by a mild delirium At 1 P M, the serum which I had ordered the day previously having arrived, I again injected 10 c c with most happy results Within two hours the heart was again beating naturally and the symptoms gradually subsided In twelve hours the temperature was normal, the pulse only slightly accelerated and the tenderness all gone I then injected 5 c c as a prophylactic against further exacerbation and in twenty-four hours I again repeated the dose The patient made an uneventful recovery desquamation taking place within twenty-four hours from the last injection

Within a few weeks I was called to attend a woman suffering from puerperal fever From the clinical picture presented, as well as from facts surrounding her confinement, there was no question in my mind as to the diagnosis of streptococcic infection Her temperature was 104 5, her pulse 150 She was a young woman of robust constitution, and afforded an excellent opportunity for the demonstration of the efficacy of antistreptococcic serum in this type of puerperal infection Ten c c of Parke, Davis & Co 's serum was injected, which was repeated in twelve hours In twenty-four hours from the second injection the patient was absolutely well, no indications of the previous infection being in any way manifest I have used the serum in a number of cases with results varying in direct ratio to the positiveness of my diagnosis In all cases where I knew that the infection came from the streptococcus erysipelatus, the results were uniformly good

Dr Madden handed me the following report of a case which he exhibited before the Milwaukee Medical Society

L A M, 40 years of age, subject to repeated attacks of facial erysipelas during the past four or five years, has had eight attacks of considerable severity The disease generally began on some point of the face and extended over the whole head, on two or three occasions involving the neck and one shoulder The length of these attacks varied from fourteen days to two and a half months About February 1 a characteristic attack began on the right ala of the nose, extending upward and backward over the right cheek The patient applied for treatment on the second day of the disease. At that time the parts bore all the characteristic signs of erysipelas On the morning of the third day 10 c c of Parke, Davis & Co 's antistreptococcic serum was injected in the subcutaneous tissue between the shoulders Two hours afterward the patient declared that he felt relieved In twenty four hours the activity of the disease seemed to have completely ceased, and in forty eight hours desquamation had begun The progress of the case from this point was uninterrupted until complete recovery

In conclusion, I would say that, owing to the fact that this serum has not yet reached a state of perfection and can not as yet be accurately standardized, we are apt to meet with some failures and be subjected to some disappointments in its use A great many diseases of mixed origin are supposed to be benefited by this serum, but the results of its use must be determined by the extent to which the streptococcus erysipelatus infection acts as an etiologic factor in the disease Any disease which is caused by streptococcic infection is certainly benefited, if not cured, by antistreptococcic serum Serum which is reasonably fresh and hermetically sealed, having been properly prepared and properly inspected, is never an element of danger and may be used with impunity, in reasonable quantities, where the diagnosis is not clear, but where streptococcic infection is suspected

---

SOME OBSERVATIONS ON THE AURI ET SODII CHLORIDUM U S P

Presented to the Section on Materia Medica, Pharmacy and Therapeutics, at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7 10 1898

BY DANIEL R BROWER, A M, M D, LL D
Professor of Mental Diseases Materia Medica, and Therapeutics, Rush Medical College University of Chicago, and Professor of Diseases of the Nervous System, Woman's Medical School Northwestern University, etc
CHICAGO

Auri et sodii chloridum is a mixture of equal parts of dry gold chlorid and sodium chlorid It is very soluble in water and very easily decomposed by sunlight and organic matter, This drug is tonic, alterative, bactericidal, and antiseptic It acts on the digestive tract, in small doses improving the appetite, stimulating the functions of the liver and stomach, promoting assimilation and general nutrition The larger doses continued produce epigastric pain, nausea, and anorexia Still larger doses produce violent gastro enteritis without ulceration and salivation Six and a half centigrams (gr 1) have produced these symptoms in an adult, and this same dose has produced death in a dog in four minutes

In anemia, in small doses, it increases percentage of hemoglobin and the number of red blood corpuscles, on the nervous system, in small doses, it is a cerebral stimulant, making the mind more active, and often inducing in the mentally depressed a sense of cheerfulness, upon the spinal cord it acts as a stimulant In man it acts as an aphrodisiac, and in woman it augments the menstrual flow In large doses it produces paralysis of the central nervous system, first in optic lobes and cerebellum, then in spinal cord, and then in cerebral lobes In medicinal doses it increases urinary secretion and the percentage of urea In large doses it will produce renal hyperemia and albumin in urea

The bactericidal and antiseptic powers have recently been investigated by Prof L Hektoen, at my suggestion, and he writes as follows

May 26, 1898

Dear Doctor —Sternberg, in his Manual of Bacteriology, made the following statement of the bactericidal and antiseptic properties of chlorid of gold and sodium

	Destroys	Restrains growth
Anthrax bac	1 8000	1 40,000
Diphth bac	1 1000	1 40,000
Bac glanders	1 400	1 15,000
Bac typhoid	1 500	1 20,000
Spir Asiatic chol	1 1000	1 25,000

I have had the necessary experiments repeated by Mr Danielson, who finds that with our cultures the above figures hold good with the bacillus of diphtheria and typhoid fever as to bactericidal powers, but that the dilutions mentioned do not destroy the other germs mentioned He found that growth was delayed by the dilutions of Sternberg in the second column

Yours sincerely, L Hektoen

Shoemaker (Materia Medica and Therapeutics, 3d, Ed, p 226), quoting Calmette, says that it is antidotal to the poison of the cobra de capello Gibbs and Shurley (*Therapeutic Gazette*, April 15, 1891) demonstrated its bactericidal power against bacillus tuberculosis First by inoculating guinea pigs and a week afterward treating them with auri et sodii chloridum, limiting the lesion to the seat of the inoculation, second by putting healthy animals under treatment for one or two weeks before inoculation, and thereby preventing in these even the formation of an abscess at the seat of inoculation

The elimination of gold and sodium chlorid takes place principally by kidneys and, to a small extent, by liver and bowels There is an astonishing amount of skepticism in the profession as to this drug Some of this, at least, arises from the fact that it is very unstable, being readily decomposed by light and organic matter Sufficient care is not exercised in its combination with other drugs, or too large a quantity is ordered, so that decomposition has taken place before its ingestion, or its administration is not properly timed, so that destruction takes place in the stomach The best vehicle with which to combine it in capsule is tragacantha or guaiac resina, neither of these decomposes it The time for administration should be one hour after eating, or, better still, one hour before eating The ideal method for administration is by hypodermatic injection, the solution used being made with equal parts aqua destillata and glycerina

Syphilis—The remedy is useful in syphilis, especially in those cases in which the iodid and mercurials do not agree, or in which there is a great amount of debility Dr E F Ingals (Diseases Chest and Throat, page 448) recommends it in syphilitic laryngitis M Martineau (*Bull et Mm de la sac, de la Therap*, April 30, 1883) recommends it in cases of inveterate syphilis One of his cases, a woman in an advanced state of cachexia broke her fibula, probably because of specific change in the bone Though rebellious to other treatment, she recovered quickly and the fracture united readily under gold treatment W Hale White (Mat Med and Therap, Wilcox, 2d Ed, p 187) says it is a valuable remedy in the tertiary manifestations of syphilis, especially of the bones, and presents fewer disadvantages than does the corrosive mercuric chlorid Shoemaker (Mat Med and Ther, 3d, Ed, p 226) and Potter (Mat Med, Pharmacy and Therap, 3d Ed, p 123) both emphatically endorse it for the treatment of syphilis in its later manifestations

The drug is useful in the treatment of connective tissue hyperplasia, as in cirrhosis of the liver, interstitial nephritis, arteriosclerosis, and the spinal scleroses Millard (Bright's Disease, p 220) writes "The chlorid of gold has proved of great value in interstitial nephritis Under its use I have often known the albumin to diminish and disappear," and again, "At all events its usefulness in chronic nephritis has sometimes been unmistakable, and it is likely to prove still more useful if the patient suffers, as is usual, from nervous symptoms, hypochondriasis, irritability, vertigo, etc" Bartholow (Practice of Medicine, p 400) writes, anent topic interstitial nephritis "Better results even, the author believes, are procured from the careful and persistent administration of the chlorid of gold, or of gold and sodium" Baumgarten (Reference Handbook Medical Sciences, Vol iv p 282) writes (referring to Dana, *Boston Medical and Surgical Journal*, Oct 24, 1883) under "Contracted Kidney" Marked improvement and mitigation of distressing nervous symptoms have been observed from the use of chlorid of gold and sodium (0 005=1/12 gr) in pill after each meal Culbertson (*Am Jour Oph*, July, 1894) relates a case of albuminuric retinitis relieved by chlorid of gold and sodium W H Walling (*Medical and Surgical Reporter*, Philadelphia, 1897, Vol lxxvi), writing of sclerosis generally "I will state my belief, founded on an experience of twenty years, that gold is far more efficient than any other drug I know of"

My first experience in the use of this remedy in interstitial nephritis was about fifteen years ago The case came under my treatment because uremic symptoms had developed after severe exposure When these acute symptoms disappeared he was given chlorid of gold and sodium, and he continued it in varying doses for five years, the albumin gradually diminishing and finally disappearing Several examinations of the urine were made five years ago and no casts or albumin were found I am sure that I have also repeatedly seen advantage from its use in the early stage of posterior and combined spinal scleroses

Diabetes mellitus—J A Robison (*Chicago Medical Recorder*, May, 1891) reports two cases of diabetes mellitus cured by its use A recent communication from Dr Robison informs me that these cases continue well and that an equally favorable result has been reached in other cases

Functional diseases of the nervous system—Niemeyer (Text Book Prac Medicine, p 386) writes "I have accidentally hit upon a nervine of great efficacy in hysteria and have made use of it with signal effect in many cases" The formula he recommends is

℞	Auri et sodii chloridi	0 30 gm (gr v)
	Gummi tragacanth	4 00 gm (dr 1)
	Sacch alb q s ft in pil No 40	

Sig Begin with two pills a day, increased to eight pills daily

Mills (The Nervous System and its Diseases, p 238) writes "Sodium and gold chlorid, although it has attained an unmerited reputation in some directions, is a valuable tonic, and I not infrequently use it in the treatment of hysteria and other affections"

My personal experience is in accord with these great clinicians, and I especially desire to emphasize its value in that complexus of symptoms called neurasthenia

Tuberculosis—Gibbs and Shurley (*Therapeutic Gazette*, April 15, 1891) report twenty-seven cases of pulmonary tuberculosis treated with the drug, used hypodermatically, in doses 0 003 gm — 001 gm (1/20 gr —1/6 gr) during three to eight months, with gradual disappearance of temperature and cough, increase in weight, and disappearance of bacilli Pepper (Univ Med Mag, December, 1895) reports a case of phthisis apparently cured by the use of this drug

GOLD CURES IN INEBRIETY

Presented to the Section on Materia Medica Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

BY T D CROTHERS, M D
SUPERINTENDENT WALNUT LODGE HOSPITAL
HARTFORD CONN

Any remedy introduced, surrounded by mystery and sustained by falsehood and deception, is unworthy of notice Yet a number of physicians have expressed confidence in the value of gold as a remedy, both in inebriety and allied brain affections This theory has been recognized by reputable druggists who have prepared several preparations of gold for administration chiefly by the needle The [illegible] tions called "gold cures" whenever analyzed are found to contain no gold whatever The assertion that no chemist can ever make an analysis of such preparations is absurd As a medicine gold has been rarely used by the regular profession, In the first century of the Christian era Pliny mentions it only to doubt its value unless taken with large quantities of drink, which destroys its potency for evil The Arabian physicians for hundreds of years mentioned gold as an elixir of life, believing it of value in renewing youth and prolonging life This doubtful theory continued and appeared in old works of chemistry down to the last century No one made a test of it, but simply repeated it in terms of vague doubt The alchemist charlatans have always been defenders of gold as a remedy It is a curious repetition of modern experience that at least three much vaunted remedies contained no gold at all In 1540 Gallus, a physician of Paris, claimed to have a gold cure for syphilis and gave the formula an impossible combination Glaser, a London doctor in 1663, claimed to have a diaphoretic powder of gold for intermittent fever This was equally fraudulent and no gold was found in the preparation, although it was used for many years with great popularity From 1725 to 1780, Lamotte's gold drop was famous throughout Europe and was called a tincture of gold, but contained no gold Neuman wrote nearly two hundred years ago "Gold has been held to be possessed of extraordinary medicinal virtues, and many preparations dignified with the name of this precious metal have been imposed on the public, but the virtues ascribed to gold have apparently no other foundation, than credulity and superstition and most of the golden remedies have no gold in them " Even when gold has been employed in their preparation none of it is retained in the product

Gold is non assimilable, and its modern use is confinded to quacks who trade on the name The modern craze for gold as a remedy is simply a repetition of charlatans' schemes of the past centuries, who sought to meet and supply the demand for elixirs of life, renewing youth and postponing old age Croll, a German physician in the sixteenth century, mentions over a hundred different preparations of gold, each if made by the formula would be absolutely free from gold This was illustrated in the modern gold cures, which from their names were found to be chemic impossibilities Their value in inebriety depends on credulity A yellow mixture of some vegetable extracts injected in the arm, followed by general relaxation and diaphoresis so profoundly impressed the inebriate chemist that he has ignored all teaching and experience for the belief that the hidden virtues of this drug have been discovered and will revolutionize pharmacy in the future I have tried three of the known preparations of gold made by reputable authorities, on cases of inebriety, with no results whatever When strychnin, cinchona and other remedies were given, associated with gold, the effects were marked The same results followed when gold was not used Infusion of cinchona in large doses at frequent intervals resulted in rapid subsidence of the drink craze and a distaste for both the flavor and effect of spirits Injections of gold were not noticeable for any effects on the taste or desire for spirits By impressing the mind of the patient with profound conviction of the value of the drug, and detailing the expected results which would follow, and by using colored water the exact effects would appear In some cases this impression is so powerful as to materially change the disease Supposing gold to be used, it must be combined or given with some other drug of pronounced effect on the body, or preceded by expectancy and credulity, to be followed with any results This would be the same in any other disease of the body, to specialize any effects from the drug alone would be impossible Inebriety is more than alcoholism, it includes disorders of which the desire for spirits is only a symptom The real trouble is some central disease of the brain so complex and obscure that no drug or therapeutic agent can reach it specifically For a quarter of a century a great variety of remedies have been used in inebriety, with the same results as in all other empiric efforts to reach an unknown disorder by remedies whose action was largely unknown Some drugs like strychnia have some influence in checking the drink symptom, but beyond that nothing is known

Gold, whose effects are unknown and even to its defenders are surrounded by mystery, can not possibly be of any service in checking an unknown disorder Its use must be empiric and irrational always, except as a mental remedy to influence the mind Experience indicates that it is extremely doubtful if any remedy exists for this obscure neurosis of the brain Combinations of therapeutic measures are valuable and their action marked in many cases, but no single drug can have any curative influence The checking of the drink symptom is the same as using opium for pain, leaving the cause uninfluenced On general principles, gold or any single drug can have no specific influence in cases of inebriety and all specifics—either single remedies or combination of remedies—are fraudulent and empiric Inebriety is not reached by drugs alone or special, concealed plans of treatment It is a neurosis to be treated as other affections of the brain and nervous system Even under the most skillful care, with the best appliances known to science, it is often incurable and only temporarily influenced by therapeutic measures The degenerations which precede and follow the use of alcohol are organic changes of cell and nerve tissue, and restoration is problematic, depending on causes and conditions largely unknown, therefore, the discovery of a remedy to check decay is impossible with our present knowledge of medicine It will require a century of study and experiment before we can speak positively and authoritatively on the pathology and therapeutics of inebriety Yet a number of men are confident that drugs are found—or will be soon—to cure and restore the inebriate to health again This expectation is met in the gold cures, where color and price are accepted as evidence This, with the hysterical assertions of cure and statements of health, reiterated with great positiveness, becomes a mental contagion difficult to resist by unstable defective alcoholics The acceptance of this testimony by persons not inebriates is ignorant credulity difficult to explain Why gold should have any influence in these complex drug neuroses, and not in the more common affections is a mystery, why the use of gold should be confined to irregular and doubtful practitioners is also a mystery Why should gold be wanting in the preparations said to contain it? Even when present, its combination with powerful drugs makes it difficult to know the value of any one of them, unless the physiologic effects of that drug appear

A physician who reported ten cases of inebriety cured from the use of gold used barks and strychnia freely at the same time, and yet seemed to think the action of gold was prominent Another physician used colored water injection as gold and impressed the mind of the patient with the certain effects which would follow The drink craze subsided and the patient recovered In many cases under my care, who have been cured in the gold cure asylums at different times, there is concealed periodicity The drink symptom is limited, and disappears naturally both with and without drugs Such cases always make rapid recovery from the use of any drugs, and assert their final cure most positively They pose as examples and illustrations of the effect of remedies, and the medical man becomes bewildered with the faith of a new discovery of some new effects of drugs If it is gold or any unusual medicine, he is more convinced These cases continue cured for irregular intervals, then relapse again and after a drink paroxysm of uncertain duration recover The first subsidence of the drink storm makes them willing to be treated medically Or when forcibly taken away and put under treatment they suddenly acquiesce, and after the first few days recover, no matter what is given This is popularly called the sobering-off process, and in all the quack asylums is limited to four weeks It is not scientific treatment, but a mere preliminary to the full restoration, which only comes from months and years of medical care The use of gold in this period would not be a final test, and its virtues could not be known from its supposed effects at this time There is no gold cure for inebriety There are no facts to show that gold has any value in this disease All the assertions and statements concerning gold as a remedy are delusions, and will not bear the test of critical examination

THE TREATMENT OF INSOMNIA

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1897

BY ROBERT T EDES, M D

JAMAICA PLAIN MASS

Insomnia is, of course, only a symptom but, like many other symptoms, it occasionally stands alone as representing some functional disturbance of which we have no other means of information When we speak of the treatment of insomnia as such, we ought not to include the treatment of the pains or discomforts from various known sources which may keep the patient awake, or of many forms of insanity, of delirium tremens or other kinds of poisoning

This narrows our limits very much, but at the same time makes the problem more precise The practitioner or writer, however, does not get rid of its difficulties by these exclusions, for many of the cases which present no other important symptoms, so that the patient has nothing to tell as to his bodily condition except that he can not sleep, are more difficult to manage successfully than one where we can put a finger on some definite disturbance that is a sufficient cause For the treatment of insomnia does not consist in making a patient sleep for one, two or a dozen nights by the use of drugs, but in getting his brain into such a condition with or without drugs that he goes through the normal, regular alternations of sleep and wakefulness, of cerebral activity and repose without special assistance but simply as a part of the physiologic functioning of the brain

The first thing then to be done when one applies for the relief of insomnia, is to determine whether it is insomnia at all in this narrower sense that is, whether it is not possible to find a cause in some irritation outside of the brain, some disorder of the digestive or circulatory system, some accidental disturbance, which prevents its coming to its normal rest, or whether its abnormal activity is not the accompaniment or precursor of some more defined and perhaps serious form of mental disturbance The expression sometimes used by patients, that they will go crazy if they can not sleep, is not always to be looked upon as a mere exaggeration, for although fortunately in the great majority of cases it is so, yet the possible warning should not be overlooked If you find no such specific cause and ask the patient what prevents him from sleeping when the proper time comes, he is likely to answer, "I do not know I simply can not go to sleep," or else, "I get to thinking and can not stop "

There is no theory of sleep which is thoroughly satisfactory, and it is by far the most probable that the changes in the cerebral circulation which have been observed are the results rather than the causes of diminished activity Still, those theories which connect the varying conditions of sleeping and waking with the state of the blood-supply to the brain, or even to certain parts of it, and its control by the regulation of the quantity going to other parts or to other organs, make the most useful working hypothesis in many cases of insomnia But it would be as absurd to expect it to cover all the ground and to stand the test of therapeutics in every direction as it would be to look for exactly the same conditions in every case of paralysis, or neuralgia, or tremor That the surface of the cerebral hemispheres is usually in a condition of relative anemia in normal sleep and also, as a natural consequence, that other parts of the body and in particular the skin, as recently shown by Howell, are apt to contain more than the usual amount of blood, are tolerably well established facts But congestion of the brain, although certainly not a condition of normal sleep, produces symptoms not very different from it, and on the other hand, cerebral anemia, whether as a part of general anemia or only local, gives rise to symptoms just as far from normal sleep as those dependent upon an opposite condition of the blood supply It is probably just as true in insomnia as in many other visceral states, that the demands of the nervous centers regulate the supply of blood, rather than that their activity is dependent solely upon vasomotor conditions which are themselves independent of the needs of the tissues

So far as the action of drugs may throw some light upon the relation of vascular tension to sleep, there is certainly an approach to the rule that many of those drugs which tend to relax it, like alcohol and chloral, are also under favorable circumstances hypnotics, while those which raise the general tension like the theine group and cocain are decidedly promotive of wakefulness But there are so many exceptions, and the hypnotic and vasomotor effects are sometimes so distinctly separate that it is not very easy to suppose that the relation of causation is an invariable or very close one

---

[NOTE —A paper of which this is to some extent a revision was read to the Section on Therapeutics of the British Medical Association at Montreal and published in the British Medical Journal for Oct 2 1897 as having been read by Dr R Ferguson of Western University The error was corrected in the index of the volume but notwithstanding several notifications not in the text of any succeeding number]

Digitalis, which raises the general tension more persistently than almost any other drug, does not specially tend to wakefulness The nitrites, which diminish it extremely and with a rapidity varying according to the basic combination, are not hypnotics, and in particular the amyl salt, which produces vasomotor paralysis with such extreme rapidity that we might reasonably expect it to be not merely a hypnotic but an anesthetic, has no such effect in its early stages when the paralysant action is at its height

Aconite, which in poisonous doses is such an extreme paralysant of the circulation, is not a hypnotic Even in the instances where moderate vascular relaxation and drowsiness are among the consequences of the action of the same drug, the relation in point of time may not be a close one Chloral, which even in small doses is not only among the most certain but the most prompt hypnotics, produces an initial rise which does not pass into depression until a later stage or with larger doses Alcohol, on the contrary, produces a speedy vasomotor paralysis of the superficial vessels, as may be seen in the flushed face and general moisture of the skin, at a time when the brain, especially in its motor functions, is in most rapid, if not most accurate, activity

Of course, it is possible, by assuming in some cases an alternation of cerebral and general vascular tension and in others a coincidence, to reconcile some of these apparent contradictions with the general theory of sleep as due to cerebral anemia, but this assumption, which even if possible or probable is certainly unproven and capricious in its application, can not be regarded as at all satisfactory, Waking and sleeping undoubtedly indicate the normal rhythm of cerebral nutrition, the alternation of waste and repair in the nervous substance itself

The rhythmic curve is a function of several variables and probably not identical in form in all individuals One of the most important of these is undoubtedly the condition of the cerebral circulation as controlling the supply of nutritive material and also the balance of pressure between the blood and nervous protoplasm Beside this, however, there are two laws of nervous activity, partly dependent on each other and partly opposed, which are probably not controlled by the condition of the circulation, at least, that is, when it varies only within the usual limits 1, the tendency of nervous force to discharge itself along the same paths with constantly increasing ease, i e, the formation of habitual associations of ideas and movements, 2, the tendency to rhythmic action, i e, excess of expenditure over income during a certain time to be made up by accumulation during rest

If we have the first of these, as applied to the attention or to some limited center of cerebral activity, gaining the ascendancy over the second, so that the action does not cease at the end of the proper time when the reserve of energy is running low or become transferred in a lower grade to some other region (sleep with dreaming), we have insomnia, which is only slightly affected by the condition of the blood supply

In treatment of chronic insomnia, in the first place a normal and sufficient general nutrition is to be looked out for as the basis for normal cerebral nutrition, but this does not necessarily imply the stuffing process A useful criterion is the body weight in reference to the height and usual or normal condition of the individual, and diet is to be regulated on this basis Secondly, the distribution of the blood is to be equalized, with the balance however tending to anemia of the brain rather than the reverse, though by no means to the extreme The derivation of blood may be accomplished by hot baths to the feet, or the lower half or even the whole body, emphasized if necessary by a little mustard The well-known expedient of a small amount of easily digestible food just on going to bed or on waking up in the course of the night, probably acts to a considerable extent, at least, in the same way The hot toddy, which also keeps coming up in the papers as a new discovery, adds to a slight direct narcotic effect the early vasomotor dilating action of alcohol

Another illustration of the same influence is to be found in the intense drowsiness that comes over one who has been for a long time in the cold and who sits down in front of a cheerful fire, when the blood previously driven to the interior of the body flows outward again as the arterioles dilate

Cold feet are often an accompaniment or partial cause of insomnia, and it is well to promote the circulation in them by a hot bath for five minutes, followed by a short cold douche and friction, rather than to simply attempt to warm them by hot bottles and the like The cold pack is a more extensive application Two methods described by Dr McAllister at Montreal, as useful in the case of students unable to sleep while cramming for examinations, undoubtedly owe their power to the production of a general vasomotor reaction following the brief superficial application of cold The first of these was the very simple plan of parading the room absolutely naked, and the second, wringing out the night shirt in cold water and resuming it with the addition of a sweater

There seems to be a certain medium degree of activity in the cerebral circulation necessary for normal sleep, and it might be expected that it would be so On the one hand the production and discharge of nervous force, resulting in cerebral activity and wakefulness, can hardly be prevented while the neurons are being bathed by a rushing current of highly arterialized blood On the other, sleep is not simply and solely a condition of exhaustion It is the preparation for waking activity and the occasion in which the storage of potential energy for future use must for the most part take place This of course can not be accomplished unless the cells have presented to them a supply of nutriment for building up again their wasted structure The promotion of the general nutrition is of great value in the treatment of insomnia, especially of the chronic form Sometimes it is sufficient without the introduction of any more specific measures in restoring the normal function But while it is necessary that suitable nerve food should be prepared in due quantity and delivered, speaking both literally and figuratively, under due pressure, yet a third condition is quite as essential, namely, that the nerve centers themselves shall have the power properly to dispose of it, that is, absorb and store it People lie awake when the extremities, the skin, the viscera, so far as any one can judge, are properly supplied with blood, and when everything seems conducive to its orderly distribution, everything, that is, except the condition of the brain itself Either an excitement which can not be abated or an excitability which makes slight disturbances into great ones drives away repose, and an active congestion is the result of the too long continued demand upon the brain, or, much more probably and usually, upon some quite limited portion of it which is the center of disturbance and prevents the repose of the whole

A brain in perfect health arrives gradually at a condition of fatigue which more or less peremptorily compels sleep, and the more so the longer the period of deprivation But sometimes the brain or some part of it does not follow the laws of fatigue and is capable of working, or rather insists upon working, in the same direction it was following when work should have ceased The rate of production is undoubtedly low and in most cases, so far as any useful thinking is concerned, none at all, but the condition is not one of rest It is much as we might imagine would be the case in a mill somewhat worn and with a water supply insufficient for continuous working, if the gate got out of order so that the pond could not fill up Then a little stream of water, not enough to grind any corn, might keep the wheels moving and prevent proper repairs or the accumulation of enough power to do any good The proper thing to do in such a case is obviously to fix the gate in complete order, but if this for any reason can not be done, it may be proper to stuff it full with something or other to save the water and stop the mill for repairs When the current of wearing thoughts will not stop, we may occasionally stuff the gate with hypnotics

Cases where sleeplessness results from adequate causes—pain, discomfort or extreme sensory irritation, bright lights, loud noises—are hardly to be reckoned true insomnia at all, but the line which separates the adequate from the trivial varies greatly according to the makeup of the individual, and in the same person at different times The psychic element is very distinctly shown in the great diversity of effect produced by disturbances according to the mental attitude of the would be sleeper A noise which he considers perfectly legitimate or for which he feels no responsibility is much less likely to keep him awake than those which come closer to his sense of the fitness of things or his personal feelings, though in themselves no worse in respect to loudness or quality, like that of the absurd dog who bays the moon, or the neighborly cough for which he has himself prescribed ineffectually, or the single mosquito he has made up his mind to kill This is not the same state of things as is investigated by the psychologists, who take the loudness of the noise (dropping of a ball) necessary to awaken the sleeper as a measure of the soundness of the sleep

Cases have been observed where, several of the senses being wanting, a temporary stoppage of the channels of the remaining one has resulted in sleep within a few moments, but it is a very common observation that noises which are continuous and to which one has become accustomed, and for which he no longer waits, cease to have any effect upon a sleeper except on their sudden cessation, which then acts as the irritant It is necessary to bring the *attention* to rest

That a certain thin streak of waking consciousness may be made to run through the sleeping condition, perhaps always to some extent does so, is shown by the ease with which many persons can wake up at a predetermined hour

It is probable that the sensible fatigue of mental labor depends not so much on actual cerebration, the association of ideas, as in forcing the work to continue in certain definite directions without regard to outside distractions After a time this becomes more and more difficult, and stronger and stronger irritants are necessary to retain the attention Thus we have under normal conditions the soothing effect of monotonous repetitions as of music, the prosy speaker, the more or less intentional hypnotist In normally going to sleep the attention, either because too much fatigued to act longer or failing to receive adequate stimuli from without, ceases to exercise its control in co ordinating the intelligence received from the special senses and from the various departments of the brain Cerebration dissociates itself from the recent memory and from the data of sight, hearing and feeling, as they are rapidly becoming blunted Definite thinking becomes dreaming Probably every one has noticed in himself the process of going to sleep carefully enough to know that the rapidity of the coming on of full sleep varies greatly, and while one may, as the phrase goes, drop to sleep as soon as the head touches the pillow, there is usually an interval in which real impressions are mixed with the images of dreams, and even in quite sound sleep the current of the dreams is more or less influenced by bodily sensations Attention should be withdrawn, if possible from habitual disturbing and anxious thought, not just *at* bedtime, but *before* it, and the interval should be employed in some entirely different occupation

True insomnia, as distinguished from an interference with sleep by special somatic causes, seems to consist largely in the attention refusing more or less absolutely to surrender its directing and controlling power over the action of the brain Perhaps the associational centers of Flechsig may, by too long continued and intense activity without rest, or a current of ideas confined within narrow and monotonous limits, get into a condition analogous to that of the motor centers in writer's cramp or chorea

The products of a partially exhausted cerebral activity, which should be allowed to float vague and purposeless, calling for an expenditure of energy much less than the nervous tissue is capable of reacquiring during the same time, are still more or less held together and intensified, so that the potential energy of the nerve centers is drained away as rapidly as it accumulates, the output exceeds the income, the patient gets but little rest, and arises unrefreshed It may be remarked, however, that the effect of two or three nights of this form of insomnia is less absolutely and thoroughly exhausting than the same period of enforced wakefulness under great pressure, as for instance, that of a sentry, a nurse, or an engine-driver working overtime, although the latter may occasionally pass into the former, as an acute disease into a chronic

A purely experimental want of sleep produced by constantly waking the persons experimented upon, although to be sure assisted as far as possible by themselves, seems to have produced singularly little disturbance in nervous or cerebral function and to have been recovered from with an amount of extra sleep much less than that lost, varying from 16 to 35 per cent[1] In these cases, however, the mental strain in the form of anxiety or responsibility was almost *nil*, and it is not difficult to understand how the effect upon the reserve supply of nerve force may have been correspondingly less

---

[1] G W Patrick and J Allen Gilbert Psychological Review [illegible]

A plan sometimes resorted to in desperation by victims of insomnia, that of producing great bodily fatigue, as for instance by a walk far beyond the usual habit or ability, is an extremely bad one and usually fails entirely of its object As with the circulation, a certain medium degree of fatigue is required for the best kind of sleep, and if increasing the burden is to be of value, it must be shifted so as to moderately fatigue new portions of the brain, and not deepen the old ruts from which it is already too difficult to dislodge the current of the thoughts Mere labor which fatigues the muscles without engaging the attention in something outside the fixed and disturbing current of associations does not fulfil this indication

At Montreal, Dr Learned of Northampton suggested successive series of slight movements of separate groups of muscles, raising the head from the pillow a certain number of times then one arm, one foot, and so on, is much nearer to the object sought, since it requires a certain amount of mental effort and attention to carry out the plan properly, and when the proper point is reached the patient is already in bed to avail himself of it Reading one's self to sleep with a suitable book is a common and commendable device The book, however, is not a matter of indifference It should not be at all in the direction of one's anxious daily occupations, nor sufficiently exciting to set up a train of thought intense enough to be itself a cause of wakefulness and, on the other hand, it must have enough interest to take the mind away from the previous one Probably nothing could be more valuable and efficient were it generally available, than music, which would, however, require a delicacy of adaptation to the individual case that would greatly interfere with its practical applicability

The prescription most frequently made for chronic insomnia, and in most cases undoubtedly the best, is that of complete rest or a vacation, recommendations more easily given than taken Absolute vacancy of mind is talked about but never artificially attained, and relief from mental activity means relief from the habitual train of thought, most probably of a depressing or anxious character It is specially difficult to obtain the proper conditions at home or among familiar surroundings

A vacation in the country, real country if it can be had, is by far the best method of getting the necessary diversion, but here also there is a choice The disturbances which drive away sleep come from within, and the occupation of the vacation must be such as will displace morbid activities by healthy ones, not intense but sufficient to predominate If the patient has nothing else to think about he will be sure to think about his troubles Black care may sit behind the horseman or beside the lounger on the hotel piazza Of course the morbid train of thought may be difficult or even impossible to displace at once, but life in the woods, with adventure enough to command the attention of the invalid in an entirely different direction, is as likely to do so as anything The psychic as well as the physical atmosphere must be changed A well-founded doubt as to whether the patient is going to find any place to sleep at all is a useful counterirritant to the harrowing dread that he may not sleep after he gets there

In cases not insane, the haunting idea which stands in the way of satisfactory sleep is likely to be the fear that it will not come, or the feeling of doubt, anxiety and despair when it is long awaited in vain Insomnia and the dread of it react to heighten each other's intensity Under ordinary circumstances it is better that all thought in regard to sleep, even a slight expectation of it, should be banished from the mind, unless of course it be so firmly believed in that the element of doubt no longer exists "Sleep, like the other gods, comes when we least expect him" When this idea has been banished a great step has been taken Suggestion, as it is mildly called, not dependent upon hypnotism and varying from the gentlest of hints to the most positive asseverations, is by no means certain of ridding the patient of this dread, and it must very often be backed up with a dose of something Patients, even when they are strongly suspicious, or even when it is acknowledged that the medicine ordered will not be a powerful one, are reluctant to have it omitted altogether and be left to their own resources

A placebo or half placebo, as some of the mild hypnotics, and even some of the others when given in very small doses, may be called, ought always to have a reputation behind it, whether deserved or not, if there is any chance of the name becoming known, lest a highly intelligent patient, as such patients are apt to be, or an officious nurse, should look it up in a medical dictionary, which for practical purposes, whatever doubts may be justifiable from a scientific point of view, should give out no uncertain sound Hence part at least of the value of lactucarium, lupulin and the hop pillow The knowledge that a powder is lying on the chimney-piece, or the assurance that a provisional order will be left on the night-nurse's book, has a tranquilizing effect highly desirable

A graduated series of powders, with sugar of milk to maintain the bulk, and enough quinin to maintain the taste, beginning with a full dose of sulphonal and ending with none of it, is a convenient way of ridding the patient of the drug habit without the disturbing apprehension consequent upon the brusque statement that he must get along as best he can without any drug

Hypnotics may be roughly divided into two classes Those which diminish the nervous irritability which keeps the patient awake, and those which distinctly, though perhaps not profoundly, narcotize the nervous centers

The most typic of the first class are the bromids, among which I have never abandoned my preference for the potassium salt as the most powerful, believing that the fear of any depressing effect of the basic element upon the heart is purely imaginary, at least in such doses as ought to be or are likely to be used in the treatment of insomnia The bromids are better given in two or three doses during the latter part of the day, and in many chronic cases through the day, than in a single large one, although in my own person the latter plan has worked well also In cases where a good deal of nervous excitability and restlessness during the day, "nervousness" par excellence is added to the insomnia, a bromization lasting a few days or a week or two is occasionally admissible The bromid of potassium, under circumstances demanding mental activity, even in considerable doses, is not a distinct hypnotic, although when given in the way I have suggested, it will allow a patient to sleep if it does not make him do so I think the same is true of its action when given with narcotics that are liable by themselves to produce an excitant effect Opium or cannabis indica may be converted by it from an excitant to a sedative I have taken a single dose of more than one hundred grains of bromid for the purpose of having its effect on my retinal circulation examined by one of my ophthalmic colleagues and then made my hospital visit without the consciousness of anything unusual in my mental condition, or any remarkable degree of somnolence perceptible, so far as I was aware, to my internes. Yet such a dose in the evening would have given me a quiet night if undisturbed, and I have no doubt, if I could have yielded to it, would have done the same thing in the daytime. Opium, with its alkaloid, morphin, the first of narcotics, notwithstanding its undoubted power, its traditional *vis dormitiva* and the fact that sleep usually follows a sufficient dose after a varying interval, is not a desirable hypnotic in the strict sense of the word. In small doses it is untrustworthy, in many persons having the reverse of the desired effect, while in large ones its disadvantages far outweigh its benefits. Where, however, the want of sleep is dependent upon pain, the case is entirely different. It would be peculiarly dangerous in a case of neurasthenia, and I can hardly think of circumstances which would justify its use in a case of pure insomnia. Cannabis indica is hardly a hypnotic at all alone or at least takes a long time to produce real sleep, but often does well in combination with bromid. I have used it occasionally alone with good effect when the dreams were depressing or annoying with the result, or coincidence, of their changing their character for the better.

Chloral, I think, has gone largely out of use. Introduced as an anesthetic, then freely used in quite large doses as a hypnotic, it has been to a great extent abandoned for safer if less powerful drugs, and I judge from the catalogues of drugs given me by patients that my opinion of its danger and uncertainty is shared by other physicians, though under the misnomer of "bromidia," which seems to obscure even in the professional mind the exact character of the preparation, it often appears upon the list of the narcotic "fiend." Of the immense number of other hypnotics of recent introduction, mostly of coal-tar or alcoholic origin, each of which has in turn been brought forward as agreeable, certain and free from danger or disagreeable after effects, I will only mention three.

I do not believe that the hypnotic is yet discovered or ever will be, which is at once trustworthy as producing the desired result and incapable of producing any unpleasant after-effects. Sulphonal comes as near to that standard as any drug with which I am acquainted, and used with care is little likely to do harm except that which attaches to any habit of the kind or dependence upon artificial aids to sleep. Nearly all, perhaps all, the cases, which, considering its widespread use, are not numerous, where dangerous conditions as evidenced either by hematoporphyrinuria or by long continued subnarcotic effects have arisen, are the results either of doses singly too large or administered too close together, not allowing the blood to be free from it in the interval. The same remark might undoubtedly be made of other hypnotics. Its correctness may be shown by reference to the discussion at the Montreal meeting.

The tardiness and permanency of the action of sulphonal, undoubtedly a consequence of its difficult solubility and slow absorption, can not be looked upon as a disadvantage when properly allowed for. A second good night without a renewal of the dose, is by no means an exceptional occurrence even when the dose has not been excessive. It seldom fails in the dose of one gram if given well dissolved and early enough in the evening. In dose of thirty centigrams or less it is somewhat of a semiplacebo. The full dose should not be repeated on the same night, and it should not be given continuously, that is upon successive nights for any length of time. If its use is to be prolonged beyond an emergency period of four or five days the interval should be more than forty eight hours.

Trional is more soluble and rapid in its action but seems to enjoy most of the advantages of sulphonal except the important one of having its effect last over two nights.

The peculiarities of each may be best utilized by reserving the sulphonal for a patient who has not slept for several nights and who, it is pretty clear, is not going to get a good night unassisted, so that the medicine may be given early, namely at 6 or 7 P.M., in order that its effect may be developed at the regular time for going to sleep. Trional, on the other hand, may be kept for a case where sleep is likely to be well begun, but where it is likely to be broken off very early in the night and not renewed without a hypnotic. It is the preferable of the two for a provisional prescription, since the dose may be given at any time in the night necessary and the effect will not be too far distant. Paraldehyde is a rapidly acting and safe narcotic, probably coming much closer in its mode of action to alcohol than the coal tar preparations. I have seen a case closely resembling a mild delirium tremens from the continued use of the drug in the hands of a patient not under professional care. The extremely disagreeable taste and smell may or may not be an advantage according to circumstances.

THE CONTINUOUS USE OF DIGITALIN IN THE VASOMOTOR AND CARDIAC LESIONS OF SENILITY

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty-ninth Annual Meeting of the American Medical Association, held at Denver, Colo., June 7-10, 1898.

BY HENRY BEATES, JR., M.D.

PHILADELPHIA, PA.

Senility embraces that period of life during which one or more of the functions, as well as nutritional metamorphoses, when compared with the manifestations of the vital unit possessed by the individual are recognized to be prematurely waning, and thus many are the instances of men and women, who, being endowed with vital energy sufficient to enroll them among the normal activities of advanced being, remain more or less disabled or invalided because of this premature failure on the part of some special organ or system to adequately discharge function. This retrograde process has an insidious origin, manifesting itself much earlier in life than we are prone to imagine, and is primarily operative, as a rule, in the vasomotor system. This *great* system has *not*, as yet, received the attentive study it should, and its direct relationship to functional activity, whether it be of brain or special sense or organ, is such that it is not an exaggeration to state that life itself depends thereon.

Active nutrition, then in the fullest sense of the term, is that condition which determines the normal relationship of function to vital u[illegible] is [illegible]ately associated with the perfect ful[illegible]tor function, because the distribut[illegible] cell, organ and system is dirc *physiologic integrity* of this *nervo-sanguineous* system The first physiologic symptoms of senility will almost always be found with, some portion of the vasomotor system, and that which is most objective consists in preternatural fullness of the superficial veins This condition is indicative of far more advanced, although not visible, alteration of the minuter radicals, both of the arterioles and venules, and when present for some length of time, is associated with the symptoms of diminished and impaired function, therefore, we have slight defects in intellection, the details of everyday life are forgotten, and the victim finds it necessary to utilize the "memorandum tablet," instead of relying upon memory Sleep is less refreshing and is interrupted by slight insomnia Some failure in vision and obtunding of hearing co-exist, while respiration is habitually augmented in rate, and the ordinary activities of life, formerly free from any sense of discomfort, are associated with more or less dyspnea The digestive functions are all less active than before, and the disturbances especially noticeable are those accompanying passive hyperemia and the consequent diminished absorption The disturbances of hepatic functions manifest themselves in paroxysmal headache and pruritus, the itching of the nose is especially noticeable, and is often contemporaneously present with similar annoyances, located in areas of the back and lower extremities Emaciation, while not marked, is pronounced, and the usual rotundity characteristic of the vigor of life, gives place to the well-known diminution in weight and wrinkling of the skin

The function of the sphincters, and especially the vesical, is markedly impaired and the passive hyperemia of the kidney gives expression to its existence by albuminuria and the shedding of casts The group of symptoms just enumerated, if the condition is well advanced, frequently assumes the clinical picture of organic disease, and thus has the writer seen what he erroneously believed to be senile softening of the brain, presenting typical symptoms, as demonstrated by a failure to recognize the members of family, inability to realize living at home, and re-living boyhood life, totally disappear under the treatment to be described, a fact demonstrating that the failure of *functional activity* may be due, under these conditions, *not* to the death of the cell, but the absence of nutriment necessary to the maintenance of its vital phenomena Of the cardiac conditions we have either fatty degeneration of the myocardium itself, cloudy swelling, or some type of retrograde change, either uncomplicated, which is exceedingly rare, or associated with gross lesions in the radicals and larger arteries Indeed, the changes in the cardiac muscle are, in ninety-nine instances of the hundred, *secondary* to a *primary* lesion of the peripheral arterial system, this fact is worthy of especial emphasis and is to be considered in formulating a prognosis, other things being equal, of any given instance Elsewhere will some facts associated with the physiology of the circulation be elaborated, and it will suffice in this connection to simply state that, in senility, the propelling power of the arterial system being diminished, by reason of its vasomotor factors, but capable of restoration to the percentage longevity of the vital unit involved, will result in the establishment of lost equilibrium The symptoms associated with what has hitherto been considered "senile heart" are, habitually augmented rate, diminution of resistance and edema of the extremities, of course, with these we have the bronchial disturbances, the falsely called "asthma," and, in advanced cases, various forms of dropsy The treatment of these cases with digitalis, alcohol, strychnia, strophanthus and nitroglycerin finds its limit of usefulness far down the scale of possible achievement, and the premature death of all such, so afflicted, has been the outcome of *secundum artem* methods

It is taught, that in the condition just described, arterial tension is increased and, therefore, digitalis should not be employed, because of producing ruptures of the brittle and overfull arteries, and otherwise endangering the life of the sufferer Careful study demonstrates that when the venous side of the circulation is tortuous and distended with blood, the arterial possesses *less* than its normal quantity; and while the aortic valves close with pronounced force, instead of being the result of *arterial tension*, this is actually dependent upon the *weight* of the column of blood, which not being propelled by what may be considered vermicular contraction, fills the non-elastic vessel as though it were an iron pipe, therefore, we have operative *weight* and not active force, and consequently *diminished* and not augmented arterial tension What obtains in the aorta is an expression of the whole arterial vasomotor system and, consequently, we have this disturbed circulatory equilibrium, characterized by distended veins and relatively empty arteries The cerebral phenomena so common in this condition manifest themselves in their worst type, by symptoms suggestive of apoplectic processes, and not uncommonly does the patient complain of localized numbness which, after a shorter or longer duration, culminates in confusion of thought, partial loss of consciousness, somnolency, confusion, loss of speech and transient paralysis of groups of muscles This condition must not be confounded with true apoplexy, by which is meant rupture of a large arterial trunk, such as the middle meningeal or striate artery, because they are dependent upon either transient *ischemia*, that is, the terminal vessels fail to transmit blood to the part on account of the lack of propelling power, or to actual ruptures of venous radicals, directly due to the overdistention characteristic of the venous side

A typical clinical illustration of an advanced case of senile cardio-vasomotor disease is that of an individual propped in a chair and completely disabled For years nearly all of the symptoms briefly described have been gradually becoming more numerous and severe, until now he is distended with anasarca, the lower extremities ruptured and oozing serum freely, while the skin is red and glossy and the seat of ulceration Respiration is imperfectly accomplished with constant effort, and is shallow and rapid, and the want of breath so marked that only a few words and disconnected sentences can be uttered at a time The bronchial area is edematous and the lungs the seat of moist râles Cough is persistent and exhausting, and sleep only indulged in for a few minutes at a time The kidneys are almost passive, and only from two to four ounces of urine are secreted in the twenty four hours Exhaustion and distress are depicted on the countenance, but to the patient are not so keenly appreciable because of a partial obtunding of the brain The cases from which this picture is drawn were the failures resulting from the *secundum artem* treatment, above mentioned, and although it is realized that the statement will be doubted, it is asserted that several who, years ago, were advanced to the stage depicted, are today free from all of these phenomena and able to be about as old, but comfortable seniles The continuous use of "digitalin" in doses sufficiently large to restore lost circulatory equilibrium, is the treatment which brought about these truly wonderful results

A few words about "digitalin" Unfortunately, this term is applied to a product in the shops which represents a complex mass or glucoside composed of one or more of the following active principles contained in crude digitalis

1, digitalein, a glucoside occurring as a white amorphous bitter powder, soluble in water and alcohol, 2, digitalin, a yellowish powder, soluble in alcohol, chloroform and 2000 parts of water, 3, digitalin German, really digitalein and an alleged inert crystallin derivative, known as digitin (this latter in a very small percentage), 4, digitonine, 5, digitalin kiliani, resolvable by treatment with acids into digitalose and digitaligenin, 6, digitalin crystallin, soluble in alcohol and ether, 7, digitalin purified, which contains, also, digitalein, digitonin and digitalin kiliani, 8, digitonin, and 9, digitoxin

When a prescription is ordered for "digitalin," the question may well be asked, what is supplied? Each of these derivatives possesses especial therapeutic power, which it is not the province of this contribution to consider, therefore, with simply indicating why there is such diversity of opinion entertained concerning the value of so called digitalin, attention is directed to the fact that that derivative, the use of which this paper is the outcome, is a so called digitalin, known as *Digitalin German Merck None other will effect the results set forth* Its dose is from one-tenth to one-half grain, from three to six times daily, as the severity of case requires

If instances of advanced disease are encountered, and dissolution threatens when first seen, one-half a grain is safely exhibited hypodermically, and repeated in one hour, after that, two grains additional are administered by mouth, in quarter grain doses every two hours, should the emergency require This bold plan has, in the writer's experience, several times averted impending death, and enabled restoration practicable, When the circulation has been restored by two or three days' treatment, the advantage is maintained by just sufficient of the remedy to secure permanent results Skillfully used, this is maintained, as the title implies, continuously A gentleman who, last October, was in the condition described and dying, has taken daily ever since, two grains a day He now walks to my office, a distance of more than one mile, and returns to his home without any inconvenience whatever After observing the effects of this treatment for years, it can be confidently asserted that *no* hypertrophy of the heart follows, also, that sclerosis of the arteries, not an expression of calcareous infiltration or atheroma, but what may be viewed as an anchylosis, so to speak, frequently disappears

This is due to the fact that the contraction and expansion essential to the calibrating function of the arteries being restored as a result of the action of "digitalin," normal functional activity and, consequently nutrition of the coats is instituted, just as a stiffened articulation, by normal movements loses its rigidity, does an artery, similarly affected The treatment must be practically continuous, because the senile changes having already become permanent are a constantly acting factor in the onward march It must therefore be constantly held in abeyance and it can be just as long a time as the life with which the vital unit of the individual was originally endowed

---

RECOGNITION OF TEMPERAMENT A FACTOR TO THE SELECTION OF REMEDIES AND THEIR DOSAGE IN DISEASE

Presented to the Section on Materia Medica, Pharmacy and Therapeutics at the Forty ninth Annual Meeting of the American Medical Association held at Denver, Colo June 7-10 1898

BY J E MOSES, M D

KANSAS CITY MO

Temperament may be defined as that quality, made manifest by the physical and mental characteristics of man There are four distinct types of temperament The nervous, the sanguine, the bilious, and the lymphatic To these I will apply the term primary, because they are the base of all the combinations or compounds met with in the majority of people A pure type of any one temperament is not often found, and when it is the characteristics are very marked For the purpose of my paper it is necessary that I describe each temperament separately, and then take up the various compounds as they present themselves Before taking up this description, I would state that I shall differ from all the authors that I have been able to consult, in that I shall consider, not only the skin, the eyes, the hair, and the contour of the face as they do, but also the brain, the respiratory apparatus, the heart, liver, and digestive organs, as elements entering into the type or temperament under consideration

Hippocrates and his followers claimed that the difference between men lay chiefly in the color of the eyes, hair and complexion, and that these could be sorted into four groups, in which all men might be placed In the original idea or arrangement of temperament the mental qualities and traits of character were not considered, thereby losing sight of a very necessary factor in the recognition of an individual A number of men have given this subject some consideration, and all have, in my humble opinion, fallen into the same error—overlooking the proportionate, relative sizes of the various organs of the body as elements of temperament, failing in this, they have been unable to present any system or plan that appealed in any measure to the medical profession as a possible aid in the treatment of disease That these temperaments are easily recognized, when of a single type, is very true, but when in combinations of two or more, they become complex and difficult to master As to a description of the temperaments, I know of no better than that formulated by Dr Alex Steward of Edinburgh, in his able work, entitled "Our Temperaments," and adding thereto certain ideas of my own which, I believe, materially influence the recognition of the characteristics of each

THE NERVOUS TEMPERAMENT,

as the name would imply, is composed of a preponderance of nerve structure and mechanical velocity of action

Physical characteristics —Light brown hair grey eyes pale, clear complexion, face tapering from a high forehead and broad supra-orbital region to a narrow chin, the nose narrow trunk slight a corpulent, often tall The chest is small, the respiratory apparatus is proportionately so, as are also the digestive and other organs of the body In other words, the nervous is in excess, proportionately, to all other elements

Mental characteristics—This temperament is impulsive, animated, quick at conclusions, excitable, readily provoked and as readily reconciled, imaginative, sensitive, fastidious, irresolute, persistent after final decisions, having great capacity for work, and will not give in even when in danger of physical exhaustion Intellectual and muscular exercises are enjoyed, happiness, from whatever source, pleases the senses, and the mind is enriched by travel, literature, or art The speech is characteristic, being rapid—often exceedingly so—frequently interrogatory and undecided The nerve energy in this type is great, and is spent without regard to results

THE SANGUINE TEMPERAMENT

This is probably the most happy type of humanity, and this temperament probably enters into as many compounds as all others combined The blending of this temperament with either of the others, or with any two of them, only adds vim and vivacity to the compound

Physical characteristics—Red or reddish hair, blue eyes, and a more or less pronounced florid complexion The face is usually square, nose, broad and alæ outspread, neck, usually short, but some are more moderate in length, build, thick set, chest, large and expansive, indicative of large respiratory organs and a large heart The respiratory effort is full and deep, affording immense oxygenating capacity, therefore a full red glow to the exposed cutaneous surfaces The abdominal organs are proportionately smaller when compared with those of the chest, though larger than those of the nervous temperament

The mental characteristics—Are impulsive, buoyant and cheerful They draw favorable conclusions without thought, are excitable, readily provoked, readily reconciled, emotional and passionate They are not enduring in work, but muscular exercises are preferred to intellectual ones They are equally happy in the pursuit of small things, as they are in the greater ones They are more happy in the pursuit than in the possession In speech they are usually firm and outspoken, but are not often minutely informed Every respiratory effort seems to intoxicate them, so they look only at the bright side of life, when left to themselves They are prone to undervalue danger of all kinds, only to rue it when too late

THE BILIOUS TEMPERAMENT

This may be termed the intense temperament, which knows no obstacle too great, nor effort too laborious to attain an end

Physical characteristics—Black hair, black or very dark brown eyes, and dark or a pale olive color complexion The face is square, nose outspread, mouth, square cut, indicative of firmness and strength of character, build, usually thick-set The chest and abdomen are well balanced and possibly slightly larger liver, the glycogonic function being unusually active

Mental characteristics—This type is not impulsive, but serious conclusions are arrived at only after due deliberation, passionate, jealous, revengeful, unscrupulous when not properly trained In business cool and wary, eager, earnest and persistent Business or pursuit of worldly gain preferred to muscular or intellectual labor, but they are able to excel in all They are happy in the pursuit of wealth or power, and also in their family relations, if not disturbed They are decided, always ready, and well-informed

THE LYMPHATIC TEMPERAMENT

This type of humanity is characterized by its absence of hurry, and its great appreciation of animal comfort

Physical characteristics—The hair may be fair or light brown, flaxen, sandy-white and thin, eyes, brown or light hazel, grey, sometimes giving the impression of a green color The corneal area is smaller, with a corresponding greater sclerotic exposure Complexion, colorless, dense or opaque The face, square, rather inclined to heavy jaws, nose, outspread, neck, short, build thick-set tending to corpulency The abdominal cavity is larger, and the digestive organs proportionately so, they are usually large eaters, tending to gluttony These people live to eat, and do not eat to live

The respiratory effort is usually shallow, the chest flat, and its expansive power somewhat limited

MENTAL CHARACTERISTICS

These people are not impulsive, but slow, and the face shows a heavy expression They come to conclusions by degrees They are not excitable nor readily provoked, they forgive but never forget They possess a certain amount of persistence, but lack ardor They are somewhat enduring in work but plodding in business They enjoy personal comfort and indulgence The speech is slow and deliberate, and when trained they are well informed Their greatest effort is in the direction of food and rest

Having carefully considered the four primary temperaments, we find that in the first type, the brain is predominant; in the second, the heart and lungs are in excess, in the third we find the chest and abdomen well balanced, with marked hepatic activity, giving strength and intensity to its individuality, in the fourth, abdominal organs, with the natural result attending—a disposition to hibernation The various compound temperaments are but modifications of the primary ones, by the union of two or more temperaments, and are indeed often difficult of recognition But this may be materially overcome by a careful examination or inspection of the body, and noting the relative size, and development of the patient, taking this into consideration with the contour of the face, the head the color of the eyes and hair, with the complexion, the subject would then be easily classed, as to the compound to which it belonged It is true, physical training and environment affect temperament and tend to modify it, but not enough so to destroy its identity

The compounds most frequently met with in this country are the nervo-sanguine, the sanguino-bilious, and sanguino-bilious with a strong nervous infusion Occasionally we find combinations of the nervo lymphatic, and also all the temperaments combined, giving us a people, the one, a constant care for the physician, while the other is a well balanced individual The first three compounds give our American people their characteristic push, speed and energy, placing them in the fore-front for physical and intellectual endurance and capacity It is not in the province of my paper to discuss these compounds in detail, but rather to apply the elements that we have furnished to a practical use in medicine

To the surgeon this knowledge is necessary, that he may recognize the degree of shock sustained by reason of injury, compared with the recuperative or reactionary power of the patient, enabling him thereby to prognosticate probable results more perfectly In his operative work he may be able to judge with some degree of certainty as to possible chance of success In anesthesia, it will indicate the element best calculated to support the patient during the trying ordeal, and which of the anesthetics offer the best results With the general practitioner it is often a question as to what complications may arise, and wherein lies the direction of danger In his dealing with the very young he may anticipate a cerebral complication, by recognizing the peculiarity of the temperament In another he may expect pulmonary or hepatic involvement and so on until every element of temperament is exhausted To the obstetrician, this knowledge is of incalculable benefit, for by a thorough knowledge of his patient, he will be enabled by suggestion, to control the expulsive effort and direct the parturient forces, so that the patient will be capable of utilizing all her energies, both nervous and muscular, to her own ultimate safety and good To the neurologist it suggests the best method of overcoming the various neuroses and reflexes, and by a proper direction of remedial agents, reconstructive and eliminative, to restore tone and vigor to the overwhelmed nervous organism To the dermatologist it affords like relief, estimating as he does the possible nerve involvement or digestive disturbance likely to exist in the premises To the oculist it is of material importance as by a prompt recognition of temperament he may the better determine the source of ocular disturbances

These suggestions will serve to give the student an idea that he may enlarge on, so that still greater benefits may accrue It seems reasonable to me that a nervous temperament would be more susceptible to affections involving the brain, in the form of congestion, anemias, etc , that would be disastrous In these people you would naturally expect various forms of neuralgias, due to the cerebal disturbances existing In the sanguine temperament the large respiratory apparatus, to properly functionate, must have at any one time a larger blood supply, than other organs, hence the greater danger from congestions or trauma from any cause This is the temperament (and compounds having this temperament in the ascendancy) that gives us the greater number of pulmonary tuberculous patients and these are people who suffer the most frequently from fatal pneumonia and bronchial affections, the bilious temperament being more frequently assailed by intermittent and remittent fevers They are not a fruitful source to the physician, for they are usually hardy and resist infection with great vigor The lymphatic temperament, by reason of its construction, is frequently the victim of hypochondriasis and hepatic and intestinal torpor, portal congestion seems almost a normal condition Fermentative dyspepsia, hepatic concretions, and catarrhal jaundice are the conditions most frequently met in this people Cardiac weakness and functional derangements are a common failure and also rheumatism and gout due to faulty elimination This temperament is most prone to sudden heart failure during acute attacks, by reason of innervation

The various compounds are modified in their tendencies, and they are the ones that give us the greater trouble and perplexity This rule may be applied to all, whichever temperament predominates in that direction will afflictions tend I believe this to be argument enough for the close observer Many will recall instances such as I have described This does not in any manner conflict with the germ theory of disease, but it does explain why some enjoy immunity from infection, while others do not

As to remedies —The nervous type stands cerebral excitants poorly because of a possible irritant congestive condition resulting, while cerebral sedatives and arterial depressants act kindly even in decided doses But when suffering from shock, such elements as strychnia, glonoin and strophanthus are strongly indicated to hasten circulatory distribution and buoy the respiratory and cardiac action The sanguine temperament is inclined to favor arterial stimulants when depression exists, and depressants in active disease conditions, with such elements as will favor the maintenance of the fluidity of the blood, also elements that control respiratory and cardiac effort The cardiac stimulants, that, have a marked effect on the peripheral circulation are well borne, but after inflammatory processes due regard must be given to deobstruants and alteratives The bilious temperament is best treated by an exhibition of antispasmodics, motor depressants and arterial sedatives Motor excitants are decidedly contraindicated in acute conditions, the indications are for general sedatives, particularly muscular and glandular sedatives The glycogenic function is most active in this temperament The lymphatic subject must be favored by catharsis, to relieve common tendency to portal congestion, and autotoxemia, but especial attention is necessary to combat the tendency to cardiac failure and cerebral stimulants are almost always indicated particularly of the strychnia class, favoring as they do the support of the cardiac and respiratory apparatus

The dosage of these remedies depends on the condition of the patient, if in the active or acute stage, pronounced doses of the remedies that are opposed to the condition existing, if passive, then small doses to give impetus by graduated stimulation of the organs involved This holds good in all the compounds as well The fact necessary to be borne in mind is, that what type of temperament is in the ascendancy, or predominates, in that line or direction will the danger lie, and the remedy and dose must be applied to these conditions If we would add to the celebrated Von Haller law, for the proving of remedies (or substances used as medicines) a knowledge of temperament we would be able to get more positive and perfect knowledge of their physiologic and toxicologic actions

In conclusion, I wish to acknowledge my indebtedness to the excellent work of Alexander Steward of Edinburgh, from which I have taken some of the descriptions verbatim, because of their terseness and clearness in the primary types, for which I wish to give due credit Some of his suggestions have but strengthened my own conclusions that a proper recognition of the peculiarities of people, both mental and physical which we call temperament, is at least very serviceable if not a factor, in the proper and successful practice of medicine Failing in this we shall but obstruct the way to the placing of our beloved profession in a line to become a positive science

IRITIS SPONGIOSA

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo , June 7-10 1898

BY ADELINE E PORTMAN, M D
WASHINGTON, D C

Prior to 1870 almost nothing is found giving more than two forms or divisions of iritis, it being classed either as syphilitic or rheumatic, there being only three forms of exudations given in the so-called parenchymatous, namely, serous, plastic and suppurative, the clinical history, cause, treatment and termination being distinct in the type

Serous —Develops slowly, no pain, normal pupil or slightly dilated, little or no injection of vessels and long duration, usually shows punctate deposit on posterior surface of cornea, aqueous humor cloudy, ends without adhesions or serious effects Treatment expectant, hygienic and constitutional, according to causes found

Plastic —Pain pronounced, onset rapid, pain referred to frontal and other branches of fifth pair, worse at night, circumcorneal injection, photophobia and lachrymation, pupil contracted, iris discolored and engorged, may be nodules upon its surface, exudation of lymph and iritic adhesions follow Treatment antiphlogistics, mydriatics and sometimes mercury

Suppurative —Iris very much swollen, yellowish tinge, and formation of new vessels in its substance, hypopyon forms, pain and inflammation symptoms much the same as in plastic Prognosis usually good

Though quite distinct types, these three forms may merge into one another, giving rise to seroplastic-plastico suppurative, though rarely, if ever, a sero-suppurative form Each form may pass over to the ciliary body and choroid, making other combinations and forms of disease

After 1870, a few cases of a form of iritis were reported, that from the character of the exudate were called iritis spongiosa, but no full description being found in any text-book up to 1880, Dr Swan M Burnett of Washington, D C after having a very severe case under his care, took pains to collect the cases then reported—less than forty in all—to give, if necessary, for future guidance of others, a name to so peculiar a form Schmidt is the first to have mentioned it, but under the head of simple iritis, of which Wecker makes mere mention in 1879

The clinical picture is pain, which, at its height, is as acute as in the plastic form Up to the time the exudate appears, it is not so intense, but after the exudate begins, till absorption takes place it is very severe The sudden relief from pain when absorption begins is a marked pecularity of this form of iritis Exudation begins with marked symptoms of irritation, in many cases very suddenly At one visit anterior chamber is clear, at the next, is filled with a gray mass of exudate In others it is extruded more slowly, usually begins in or below pupillary space and in most cases fills anterior chamber Very likely absorption had begun in cases said to be only partly filled Absorption takes place with varying rapidity, generally five to eighteen days elapsing before all traces have disappeared The course of absorption is very peculiar, and characteristic It begins always at the periphery, and the mass gradually diminishes from all sides equally, the pupil being last to clear

As to the character of the exudation, it has been found on examination in its earlier condition, fibrous Knapp, who first examined it, says "It consists of a dense network of very delicate fibrils inclosing white and red blood corpuscles and of a finely granular substance" His opinion is that when the substance is uniformly semitransparent (hyaline, gelatinous, like a dislocated lens) it probably consists exclusively of coagulated fibrin, if gray, or whitish gray, white corpuscles, which collected in clusters appear like whitish dots, yellow or yellowish green tinge indicates red blood corpuscles Alt says "The exudation has two well-defined parts, the one perfectly homogeneous, like the gelatinous exudation, the other, lens-like in shape, consists of a net-work of exceedingly fine threads of fibrin, the meshes of which were filled with exudation The two layers are the two stages of exudation so-called, at first spongy, then gelatinous" The unchanged appearance or nearly so of the iris precludes the possibility of extravasation of blood into its tissues, the iris having its normal luster, and as soon as the attack passes it is seldom discolored or changed in appearance, which would not be the case if the blood had been extruded

Diagnosis As soon as the exudate appears there is no difficulty in deciding that we have to do with spongy irritis The difficulty is not to confound it with diffuse keratitis or a lens dislocated into the anterior chamber The excessive chemosis is not present in diffuse keratitis, and oblique light shows epithelium intact When absorption begins, the sharply defined edge of the mass appears so exactly like a luxated lens that only a magnifying glass and oblique light quickly shows the error A fibrous mass in some of its parts, lack of regular outline, and peculiar mode of absorption, proves iritis spongiosa The typic form leaves iris free and normal, but it may be joined to plastic form and adhesions result No cases united to serous or suppurative forms is known As to etiology, it may arise from any of the causes of iritis—traumatic, rheumatic or syphilitic The great majority of cases reported were males

Prognosis in typic form good Treatment as in plastic antiphilogistics, mydriatics, anodynes and hot applications Absorption is naturally so rapid that mercury is not of benefit unless indicated by some dyscrasia The last case seen will give a perfect picture and history of cases in general

I J , colored, female, seen first Jan 9, 1898 Exudation in anterior chamber of left eye, down and outward from pupil, reaching slightly beyond pupil, which was small and adherent First noted trouble in the eye ten days before, pain and usual symptoms of iritis No history of syphilis January 11, under atropin, pupil dilated somewhat, but irregularly, exudate about the same January 12, the edge of exudate, which before had been undefined, is today sharply defined at the upper margin, the anterior chamber above it being clear and showing the pupil enlarged, but still some adhesions January 13, only a small quantity of exudate downward and outward January 14, no trace of exudate, pupil larger, no pain January 16, eye clear and vision about the same as before the attack This is as nearly as may be a typic case, though the exudate may be much longer in being absorbed This type, when once seen, will not be forgotten, though from any text book it has been my fortune to examine, one may not get even an idea of its real appearance

A NEW PERIMETER

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association, held at Denver Colo, June 7 10 1898

BY CHARLES H WILLIAMS, M D,
BOSTON MASS

In testing the field of vision it is desirable to have the same illumination of the test object in all parts of the field, and to be able to diminish the intensity of this illumination by a known and measured amount when we wish to test the field for white or colors in cases of beginning atrophy or other conditions where there is a marked difference in the extent or shape of the field of vision when tested with a full and with a diminished amount of light This seems to be best accomplished by making the tests in a dark room and using two incandescent electric lights of one candle power each for the test object and the fixation point A Förster's perimeter with a broad semicircular arc of hard rubber is arranged so that one lamp is placed in the center of the arc and about an inch from it, to be used as the point of fixation Slides are made so that pieces of ground glass, London smoke glass or diaphragms with openings of various sizes and shapes can be inserted in front of this lamp The other lamp is arranged in a similar way and can be moved back and forth from one end of the arc to the other, its motion being controlled by a small electric motor mounted on the perimeter and geared so that the test lamp is moved on the arc with the desired speed The motion of this lamp can be reversed at any time by reversing the polarity of the armature of the motor by means of a switch held in the examiner's hand, in this way a motion back and forth can be obtained for the test object without going near the perimeter or without taking the examiner's gaze off the patient, thus making sure that the patient does not alter the direction of his eyes during the examination

SOME SEVERE CASES OF TOBACCO AND QUININ AMBLYOPIA

Presented to the Section on Ophthalmology at the Forty ninth Annual Meeting of the American Medical Association held at Denver Colo June 7-10 1898

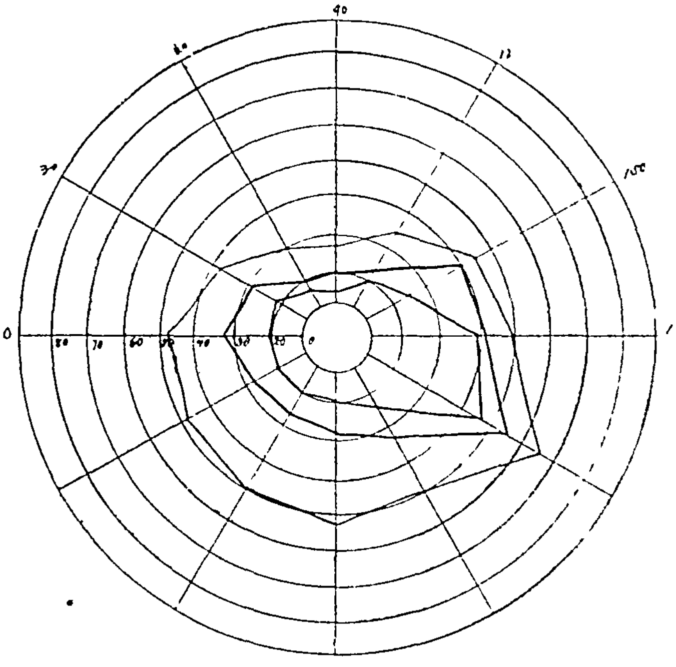
BY E C ELLETT, M D
Ophthalmic and Aural Surgeon to St Joseph's Hospital The Children's Home and the Shelby County Poor and Insane Asylum formerly House Surgeon in Wills Eye Hospital Philadelphia
MEMPHIS TENN

In presenting to your notice any observations on the subject of the toxic amblyopias, the recent exhaustive works of Wood and DeSchweinitz render references to the history and literature of the subject entirely superfluous It is from a study of the work of these gentlemen that I am enabled to appreciate the unusual features in the few cases which I wish to report, and I present them solely for the reason that they do exhibit some points a little out of the ordinary

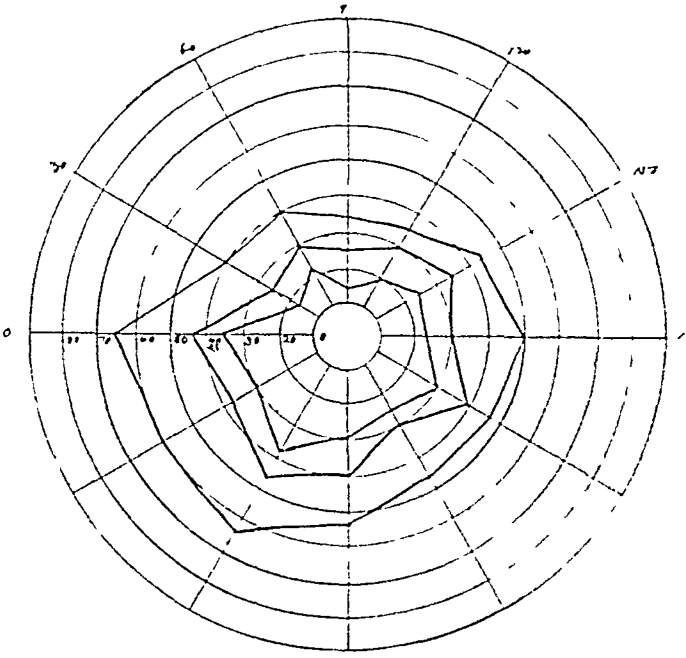
The first case was a young man of 26, whom I saw at the request of his physician, Dr Thomas Henderson, Feb 28, 1894 Since August, 1893, he had not been able to see to read, though his vision began to fail some months prior to that time Since 12 or 13 years old he has been addicted to the use, or rather the abuse, of cigarettes, consuming from ten to forty a day, and at the time he came to me he was smoking from thirty to forty a day It was his habit to awaken frequently during the night, on account of extreme nervousness, and to smoke cigarettes whenever he awoke For six years he had been a steady drinker, beginning with beer, but for the three years preceding my examination he had been more addicted to whisky, which he said he was stopping He was the picture of an alcoholic, extremely nervous and tremulous, his person and attire saturated with the fumes of tobacco and alcohol, and he often would suddenly and causelessly burst into tears

The pupils were equal and normal, and vision was 6/200 in each eye Very unsatisfactory perimetry showed no contraction of the fields and no scotoma Of this I could not be sure, as his general condition made this part of the examination very difficult, he answering rapidly and carelessly in his desire to have the ordeal terminated The ophthalmoscope showed whiteness and cupping of the lower temporal quadrant of each nerve, with veiling of the nasal edges, and the vessels were of normal size He would not consent to undergo treatment, and died of acute tuberculosis the following summer An autopsy was not obtained

The second case was that of a medical man, aged 28, whom I saw on Oct 6, 1896 His vision has been failing since April of that year, and was reduced to 20/200 in the right eye and 3/200 in the left. He read J x with difficulty, and had been compelled to relinquish a position as quiz master in a medical school on account of his impaired sight and his usefulness as a practitioner was greatly curtailed Since 12 years old he had been a smoker, at first cigarettes, but at the age of 21 he began to smoke cigars, and smoked as **many as** twelve or fifteen a



Right Field of vision of Dr W, Feb 3, 1898



Left Field of vision of Dr W Feb 3 1898

day At the time of his visit to me he was smoking about half this number For several years he has been in the habit of drinking six or eight glasses of beer a day His physical condition, except for his vision, was very good I found the same ophthalmoscopic picture as in the first case, whiteness of the lower temporal quadrant of each nerve head, the rest of the disc being a dirty red, and the vessels of normal size The pupils were normal and the perimeter showed a central relative scotoma in each eye He was advised of the nature of his trouble, told to stop both tobacco and alcohol, and was given 1/48 of a grain of corrosive sublimate and five grains of iodid of potash three times a day, and later 1/20 grain of strychnia in addition He stopped smoking and has not touched tobacco since He fought it out through a few restless days and nights and the battle was won Stopping his beer did not inconvenience him any His progress was steady, but slow October 11, O D 20/100 p O S 5/200, Nov 2, O D 20/100 O S 8/200, November 12, O D 20 100 O S 20 200, Jan 3, 1897, O D 20/70 O S 20/100, February 17, O D 20/50 O S 20/70, and he could read J i with O D and J ii with O S About March 1, 1897, he stopped treatment of his own accord, but continued to improve May 20, 1897, O D 15/20 p O S 15/20 p, could read J i fluently with each eye He now does not smoke, but drinks a little beer His vision in February, 1898, was 15/20 p, the ophthalmoscope about as at first and his fields as shown

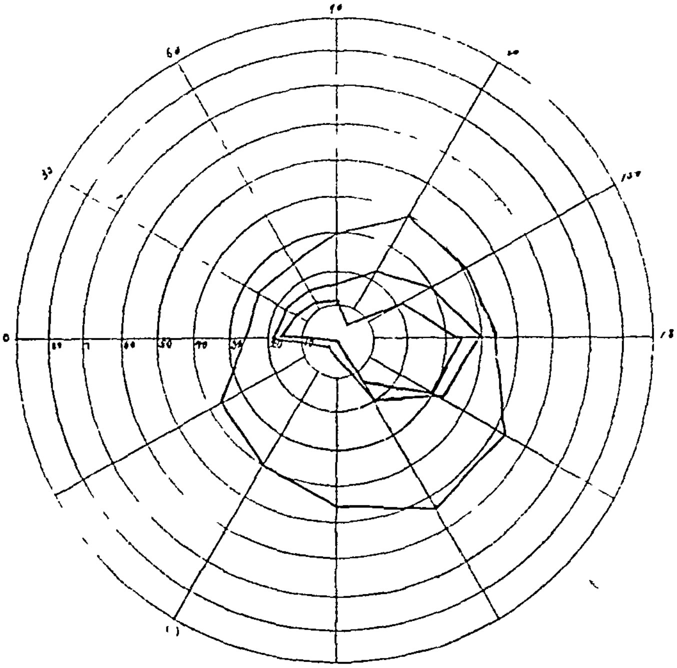
These two cases are what we must call alcohol-tobacco amblyopia, since in neither was the abuse confined to one of these substances, and we can do but little more than speculate as to the true cause of the symptoms in each case The description of the condition which Uthoff gives as being found in the majority of his 1000 cases fits these two exactly, pathologic whiteness of the temporal half of the optic papilla (papillo macular bundle) and occasionally haziness of the nerve head or hyperemia of its surface, so that we may put them down as typic cases, so far as the ophthalmoscopic appearances went

The first unusual feature is the youth of both of these patients, 26 and 28 De Schweinitz says they are exceedingly uncommon before the 35th year and Wood puts it down as rare under 40 In over 300 cases quoted by these gentlemen in which the age was given, only ten were under 30 years old Though only 26 years old, my first patient had been a cigarette fiend for thirteen years, which is about the length of time necessary to produce the condition of tobacco amblyopia The second had also used tobacco for fifteen years, but cigars for only six

Another point is the extreme, and in the second case, unequal, reduction of vision In thirty-five cases Uthoff found 6/200 the lowest point to which vision was reduced, and 1/40 (or 6/240) is put down as the extreme limit I beg to recall the fact that the vision was 6/200 in each of the first, and 2/200 in the worst eye of the second patient Unilateral amblyopia even has been observed, but it is usual to find the impairment equal, as one would naturally expect from the fact that the cause acts systemically It is somewhat unusual to find this condition resulting from the use of cigarettes, but my first patient did not use tobacco in any other form

A third case is one which I am by no means sure it is correct to place in this category, and therefore I put it apart from the others, and what comments are to be made on it will apply to it alone

C W, a mulatto boy, age about 21, was sent to me on April 20, 1898, for poor vision Since he was seven or eight years old he had had enlarged cervical glands on both sides, which had often suppurated His neck showed the characteristic cicatrices on both sides and many enlarged glands could be seen and felt Since about the same age (that is seven or eight) he had been a cigarette smoker, but never to excess His indulgence, according to his statement, had not amounted to more than a five cent sack of "Duke's Mixture" a week, which is certainly very moderate A year or so ago he had contracted a venereal sore, which made its appearance within two or three days after exposure, and disappeared at the end of a similar length of time For five weeks his vision had been rapidly failing till he had little more than light perception peripherally when he came to me Indeed, his field could not be taken with candles, which was probably on account of a large central scotoma The pupils were normal, and the nerves showed whiteness of the lower temporal quadrants In the macular region of each eye the fovea showed as distinctly as we often see it in mulattoes and negroes, and in each macular region there were pin point glistening spots, such as I have often seen at the macula and elsewhere in the eyes of negroes who have perfect sight The only pathologic condition visible to the ophthalmoscope, then, was the condition of the discs which I have mentioned The vessels were normal *Faute de mieux*, he was put on ascending doses of iodid of potash, which he bore with the characteristic complacency of the Southern negro He has gradually increased it to 150 grains a day, and I show here the field of the right eye, taken May 14, when the vision in it was 15/20 p The left eye has, with the candles, a decided relative central scotoma, but the vision has improved very little He can count fingers at one foot eccentrically with it



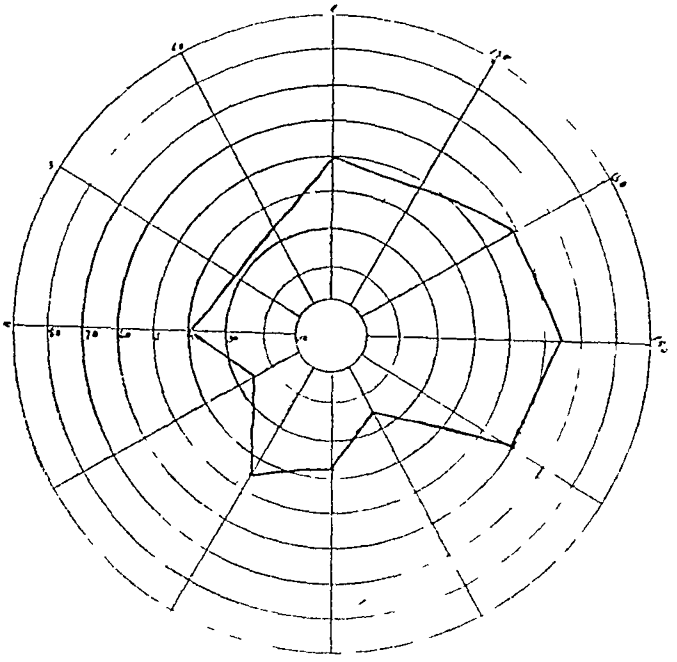
Right Field of vision of C W May 14 1898

As I before remarked there is very slender evidence on which to class this as a case of tobacco amblyopia The youth of the patient, his moderate use of tobacco, and the fact that one eye improved and the other did not, are, I think, against this diagnosis The ophthalmoscopic appearance and the lack of positive reasons for classing it elsewhere are my reasons for presenting it in this connection

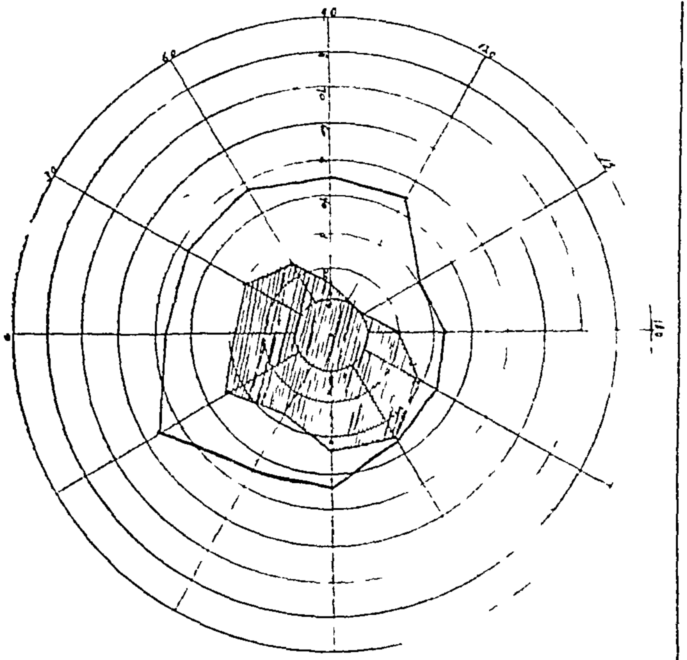
In addition to these cases I have to present the history of a fourth

F F, aged 30, was brought to me by my friend, Dr Pincus, of Memphis, with the following history Since seven years of age he had smoked cigarettes in increasing numbers and from 1890 to 1893 he smoked from forty to fifty a day In 1893 his employment prevented him smoking so constantly and he reduced his allowance to from six to eight a day, which number, I may say, he still consumes He smoked a cigar and a pipe occasionally and very seldom drank anything

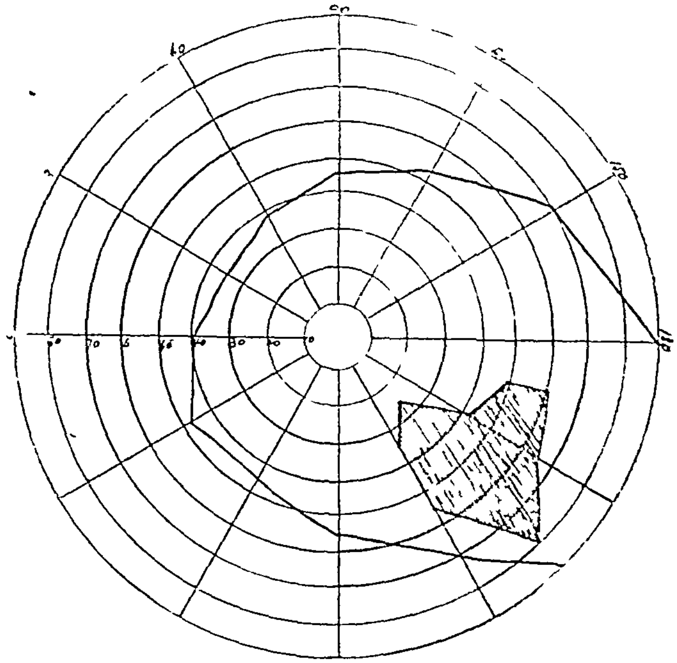
In the fall of 1894 he suffered from intermittent malarial fever of the tertian type for a month On Monday, Nov 19, at the suggestion of a medical student that he take quinin, he procured some of the sulphate and some empty five grain capsules, and mixing a pinch of capsicum with the quinin, he filled twenty four of the capsules, and beginning at 7 A M, he took two capsules every hour till 7 P M, this making the amount about 120 grains At 7 P M he was completely deaf, but the deafness passed off by 10 o'clock, and he felt no further inconvenience in any way till Thursday, the 22, when his eyes burned and smarted a little, but there was no impairment of sight. I may say here that his tertain organisms were effectually routed Friday morning he awoke with the sight of both eyes very much impaired, about as much, he thinks, as it is now He was taken to a physician about noon of that day and when he left this gentleman's office at 1 o'clock he had lost the perception of light, nor did he regain it until the end of three months He was given iodid as high as eighty five grains, three times daily, and also went to the Hot Springs of Arkansas At the end of three months, as I have said, he regained the perception of light, and from that time to the present has experienced a very slow improvement in vision When I examined him first in May, 1897, his vision was O D 7/200 O S 15/200 eccentrically His fields I here show you, and would call attention to the changes in that of the right eye with the final appearance of a relative ring scotoma Colors appear to him as different shades of light and dark Tested as for color blindness with colored wools, he matches the test skeins very well, not by color, he says but by their relative darkness I once tried nitrite of amyl inhalations according to the suggestion of Dr Kollock, of Charleston, but though vision was temporarily doubled, no permanent improvement resulted The pupils of this patient are dilated but respond to strong light and to accommodation The ophthalmoscopic picture is that of optic atrophy (white) with papery nerve head and attenuated vessels



Right. Field of vision of F F, Dec 6 1897



Left Field of vision of F F Dec 6, 1897

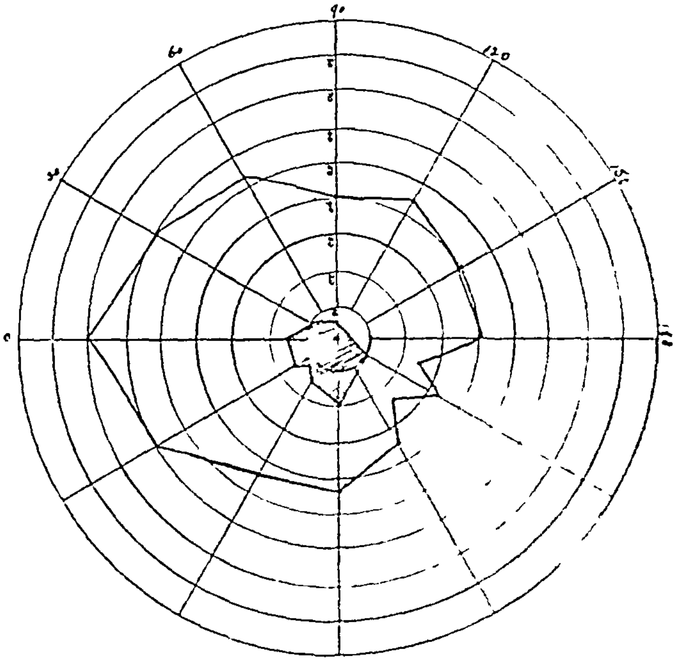


Right Field of vision of F F, Feb 24 1898

In this patient we see nerves already probably affected to a slight degree by the long continued abuse of tobacco, and further devitalized by a continued tertain malarial infection, become the victims of a large, but not enormous, dose of quinin Since this poison is more or less accidental, age and sex do not bear on the condition The unusual features of this case are the following

1 The length of time which elapsed between the ingestion of the poison and the appearance of the eye symptoms As far as I can determine the usual condition of affairs is a rapid effect on the vision

2 The severity and chronicity of the visual impairment



Left Field of vision of F F, Feb 24 1898

3 The unequal effect on the two eyes

4 The peculiar and dissimilar visual fields, presenting a relative ring scotoma in one eye and an absolute central scotoma in the other The effect on the color sense is not remarkable, considering the impairment of vision and the ophthalmoscopic appearances

SOME RESULTS IN CASES OF TOBACCO AMBLYOPIA

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo June 7-10 1898

BY LOUIS J LAUTENBACH, M D
PHILADELPHIA PA

The results here presented to you are the conclusions drawn from the various cases of tobacco amblyopia treated by me during the past seventeen years The cases selected are intended not only to call attention to the favorable results following treatment, but to serve especially as illustrations of the faith that is in me The subject has been so exhaustively handled that it is needless to theorize more, practical experience is after all our final teacher

I employ the term tobacco amblyopia to express a bilateral, retrobulbar neuritis of the optic nerve with central color scotoma, followed later by an atrophy of the nerve occurring in one addicted to the use of tobacco, and so far as known not using any other toxic agent to excess The condition may be due to a primary hyperemia of the nerve in this location—the interstitial inflammation, with later the formation of connective tissue elements followed by atrophy of the axial fibers of the optic nerves following it The primary lesion may be a direct action of the poison on a central inhibiting center followed by the phenomena above outlined—a suggestive fact in connection with this supposition being that it is always bilateral Whichever of the various theories as to its primary origin may ultimately be proven to be the true one, the lesions met with are well understood That which especially concerns us are its early recognition and curability, and the measures that conduce thereto I believe that tobacco blindness is not an uncommon affection, being far more prevalent than usually supposed It varies from a condition of but slight obscuration of vision to a complete loss of sight It is in the early stages especially that the affection should be recognized, as then the complete restoration of sight is comparatively easily accomplished, whereas in the later stages when atrophy has set in, the disease can usually be arrested but the vision can not be fully restored The reason why we find in hospital reports so very few records of tobacco amblyopia is, I think, that these slight cases go unrecognized, the condition being perhaps unconsciously overcome by the doctor insisting upon more rigid habits and alterative treatment The cases are usually recognized by the disturbance of vision observed on passing from the dark to the light, or even vice versa, by an obscuration of vision more or less constant, by perhaps even a slight sluggishness of accommodation, by at first a hyperemic condition of the outer half of the nerve, especially below, and, I fancy, a slightly sluggish pupil on varying the illumination, and by olfactory evidences of the excessive use of tobacco as well as from the history

As for the form in which tobacco must be used to bring about such results, I would say that it would have to be smoked, that is, the oily alkaloid volatilized, and the other constituents of the tobacco gasefied In my work I have never seen a case produced by the use of snuff, nor have I seen a case in which I was sure it was caused by the handling of the tobacco either in its fresh or dried state, nor have I seen a case in which there was any evidence that the chewing of tobacco has caused it I know this latter statement is at variance with that of most observers, and yet so sure am I of this fact that I allow my smokers, who are also chewers, to continue the latter if they will but stop the former Case 2 is one to whom I allowed this privilege and yet he improved from R E 6/19, L E 6/19 in three months' treatment while using chewing tobacco constantly to R E 6/6, L E 6/6

As for the age at which this disease appears, I think it well to recognize that *it is especially liable to occur in adolescence and early manhood*, on account of the greater susceptibility of the nerve structures I have found it present in a comparatively large number of patients under 21 years of age The youngest was aged 13 years Case 1 was a well-marked and typic case of rapidly progressing tobacco blindness The oldest case I have treated was 76 years of age

In regard to the condition of the pupil, I have frequently observed slight irregularities and inequalities present, and as before said, I fancy that the response to light stimulation is slightly less prompt than normal I will briefly outline a few cases and their results, making comments as necessary and will indicate later the treatment followed All the cases showed typic central scotoma with the usual objective symptoms

Case 1 —Frank A R , a school boy aged 13 years, was examined Jan 19, 1888, and presented the typic symptoms and history—a cigarette smoker, had never used alcohol , had history of increasing loss of sight during the past year Remote vision, R E 7 5/38 , L E 7 5/48 , proximate, R E 1 J @ 7—40 cm , L E 1 J @ 7—40 cm The remote vision was slightly improved by glasses Stopping the tobacco entirely and pushing the treatment the vision was raised in four months to R E 7 5/9 , L E 7 5/6, improvable with H As glasses to B E 6/6

Case 2 —Mr Thomas R H , aged 50 years, came Dec 28, 1896, with a history of steadily decreasing vision, commencing one and one half years previously He never had used alcohol in his life On his arrival I observed he had a very peculiar gait He walked with his head twisted to the side and downward, at once indicating central total scotoma, which was confirmed by taking the fields His remote vision was R E 6/10, L E 6/10 , not improved by glasses Near vision was R E 20 J @ 19—100 cm , L E 20 J @ 15—100 cm He had early noticed mists and obscurations of vision and an increasing impairment of sight Later on he began to observe that his central vision was gone , he has been compelled to rely on eccentric vision for about a year His tobacco smoking was stopped at once and he was allowed to chew although he had not done this before He had averaged over eight cigars a day, but ceased at once The treatment was pushed to the fullest extent and he was very faithful in following all my directions After three months' treatment I ordered for him B E + 2 75 for near = 1 J @ 17—45 cm His distant vision without glasses was R E 6/6, L E 6/6 This was a typic case of tobacco blindness and one easily proven, and yet by ceasing smoking and thorough treatment his remote vision was made practically perfect, his central vision being restored to him, and instead of walking with the head twisted on the body he saw perfectly well with the head erect and directed forward as natural

Case 3 —George W S , a tobacco dealer, aged 57, came to me Feb 5, 1898 , a case dating back some ten years since its origin, one in which atrophy had occurred to a great extent Remote vision, R E 3/60, L E 3/60, not perceptibly improvable by glasses Proximate vision, R E some 50 J , L E 50 J , not improvable by glasses No alcohol has ever been used by the patient, but he has been a constant smoker since he was a boy After three months' treatment and the ceasing of the use of tobacco, continuing the chewing, however, his remote vision improved to R E 6/48, L E 6/18 , with glasses, R E 6/9, L E 6/12 and his near vision with glasses to B E = 1 J @ 21—38 cm

Case 4 —Mr John R., aged 76 years, came to me March 27, 1897, with a typic history of tobacco blindness, dating back some twelve years—the observed symptoms confirmed the history He had always been a heavy smoker but a moderate drinker The condition present was one of extending atrophy His distant vision was R E 4/60, L E 2/60, not improved by glasses Near vision, R E some 30 J, L E some 40 J I could not entirely stop his smoking, but put him on the scantiest allowance possible, and instituted the usual treatment, with the result that with glasses his distant vision improved to B E 6/24, and near vision to B E = 3 J @ 20—35 cm The case is interesting on account of the age of the patient, the length of the period of involvement and the fact that despite these factors there was a marked improvement in vision

Case 5 —Mr G W S , New York City, jewelry salesman, aged 33 years, came March 8, 1894, with the typic history, fields, symptoms and appearances of a commencing tobacco amblyopia He commenced the use of tobacco as a boy and continued at it pretty continually, using at the time eight or ten cigars a day Later on he commenced to use alcohol, but not excessively His symptoms of blurred vision and obscurations, especially when there was a change of illumination, particularly when leaving the outer air and entering a room, had continued for about a year, lately seeming to get worse Occasionally he momentarily saw double, but attributed this to his stomach Remote vision, R E , 6/9 ? + 1 × 90° = 6/6, L E , = 6/9 ? + 0 50 × 90° = 6/6 Proximate vision, R E , 1 J @ 13—57 cm , L E , 1 J @ 15—64 cm The proper glasses and treatment were ordered for him and he was strongly urged to stop smoking, being warned he would go blind unless he ceased it

I saw very little of him after this, but have learned from his friends that he continued the tobacco habit until quite blind, when he consulted an Eastern specialist, who insisted on the stopping of the tobacco, but he refused to obey His vision is now so bad that he has not been able to do his work for over two years, and lately is compelled to have some one guide him when he goes outdoors This case excited so much compassion in New York City that a benefit was given him the past winter, at one of the prominent theaters there, the announcement indicating the total blindness of the beneficiary We will observe that when he presented himself his vision for near and distance was almost normal, and yet four years afterward he was totally blind

Case 6 —Mr John A Z , attorney, age 23 years, came for the first time March 23, 1893, with a typic history of tobacco amblyopia, and the examination gave absolute evidence of the same fact The blurred vision on going into the light was very marked It had been coming on for about a year Remote vision was, R E , 6/10, with glasses 6/6 , L E , 6/30, with glasses 6/12 Proximate vision, R E , = 1 J @ 12—48 cm , L E , = 1 J @ 12—46 cm After cessation of the smoking habit (he was a very mild user of alcoholics) and steady treatment for four months, he was discharged with a remote vision of R E , 6/6 , L E , 6/6, with glasses, and proximate vision R E , 1 J @ 12—50 cm , L E , 1 J @ 12—50 cm His eyes were practically perfect

He again appeared April 23, 1896, having recommenced smoking shortly after his discharge by me although I had carefully informed him as to its danger His remote vision now was R E , 6/24 ? L E , 6/24 , improved with glasses to R E , 6/6 + , L E , 6/6 , and proximate vision, R E 1 J @ 12—44 cm , L E = 1 J @ 12—44 cm After three months' treatment such as had been followed before by such good results he was again discharged as well, with normal vision, and up to this time he has not reappeared

It will be noticed that the first three cases above noted developed in those who had not used alcohol in any form Of the others none had used alcohol to excess Several of them continued to chew after the treatment was commenced and yet the vision improved In all in whom a favorable result followed was smoking withdrawn

The treatment to which I now subject my patients comprises the routine measures of absolute stoppage of smoking, the use in increasing doses of iodid of potassium, the use of increasing doses of strychnin In addition, I always order the frequent applications of hot washes to the eyes, preferably by means of eye cups I always use irritants, such as alum stick, etc , to the lids myself two or more times a week I always advise hot plunge baths if possible every night, and order that hot water, hot milk or hot lemonade be used frequently and liberally I have observed quite a marked increase in the amount of improvement developed in my cases since these latter measures were systematically added to the treatment I believe they serve to improve the local circulation about the eye as well as the general circulation, thus stimulating the metabolic processes and strengthening the activity of the secretory organs to such an extent as to the sooner relieve the system of the toxic agent as well as of the results of the perverted nutrition It may be termed a going back to the old water treatment

1723 Walnut Street

AMBLYOPIA FROM AUTO-INTOXICATION

Presented to the Section on Ophthalmology, at the Forty ninth Annual Meeting of the American Medical Association, held at Denver, Colo, June 7-10 1898

BY H B YOUNG, A M, M D
BURLINGTON, IOWA

Within the past year I have had under observation six cases of amblyopia differing in degree, and more or less transitory in character, for which I have been at a loss to give a definitive diagnosis The possibility of an hysteric origin has not been overlooked Indeed with two of the six this idea is still entertained But with the others, the presence of a particular symptom, coupled with intestinal derangement, and this more or less uniform in all, seems to allow the characterization which appears in the title of this paper I will endeavor to describe briefly these four cases

Case 1 —Mrs C S, age 40, mother of four children, hitherto vivacious and apparently healthy, aborted last May in the sixth week of her pregnancy She was making good progress toward recovery under the care of her family physician, when on the evening of the third day, without any undue flooding, pain, or other bodily disturbance, she complained of a failure to see objects distinctly—as if the lights had been turned down The next morning she could see nothing -had not even light perception I saw the case immediately and found the conditions as follows Patient in bed and a professional nurse in attendance, alarm and despondency manifest, the face was pale almost putty color, the eyes had the aimless stare and wandering peculiar to those blind from atrophy, the pupils were widely dilated and unresponsive, no complaint of pain about the eyes or head, and no hypogastric tenderness The tongue had a dirty yellow coat, and the breath a peculiar foulness of odor I wish that I could accurately describe this odor, for this is the particular symptom which these indeterminate four cases all had You have all noticed the odor of the breath in cases of extensive corneal suppuration These amblyopic cases had an odor equally putrid, but more stale and musty

Ophthalmoscopic examination was negative—the discs were perhaps a little pale, nothing more Both nurse and physician were interrogated, but the reply was in each case positive "no mydriatic medicine had been used in any way" The bowels were said to be inactive, and the appetite nil The pulse, temperature and urine were negative The odor of the breath, associated with loss of appetite and inaction of the bowels, suggested a failure of digestion, and in the absence of any structural changes in the eyes, I hazarded the opinion that if the alimentary canal was promptly cleaned out by a cholalogue cathartic, vision would probably return Calomel was given at once, and continued until the bowels moved freely (the nurse describing the odor of the discharges as foul beyond anything in her experience), with the result that on the third day the pupils reacted, within a week there was Q P L, and a month later, after correction of astigmatism, vision was $^{20}/_{20}$ in both eyes

Despite a careful dietary, however, and more or less in the way of medicine all this while, a normal appetite, regular action of the bowels, and buoyancy of spirits were not regained until two months later

In January last there was a return of all her troubles in a modified form, constipation, poor appetite, foul breath, low spirits, and vision reduced to $^{20}/_{70}$ and reading headlines in the papers Ophthalmoscopic examination was again negative The field for form was perfect, for color, uncertain The red and green squares on the perimeter targets were *not* recognized at all, but when shown in larger areas were correctly selected in a number of different shades The same line of treatment was employed as in the first attack, (pleasure journey included) and the result while more slowly attained, is the same

Case 2 —P R S, age 59, formerly a master mechanic for a railway company, consulted me for the first time in January 1893 He thought his vision might be helped by glasses The record shows that I got for him $^{20}/_{30}$ in the left eye with —1 5 sph and —0 5 cyl, axis 90, but only $^{20}/_{0}$ in the right with —2 sph on account of opacities in the posterior lens cortex In December, 1895, he came for a change of glasses He now had $^{20}/_{40}$ + in the left eye with — 2 5 sph and — 0 75 cyl, axis 90 In the right eye the lens seemed a little more opaque (It is to be noted here that from this time on Wallace's test card was used, the letters having only 4″ angle)

In January, 1897, he came again, very much discouraged over the continued failure in vision The left eye had now only $^{20}/_{0}$ — with —4 sph, and cyl as before The disc was moderately excavated and the tension was apparently too high, but no fault could be found with the pupil, ant/ chamber, or field of vision However as there was some complaint of pain at times, and the condition was that wherein one hesitates to decide between simple atrophy and chronic glaucoma, I felt that a tentative exhibition of a miotic was not out of place I therefore prescribed pilocarpin, and after some days my patient reported the situation improved both as to comfort and vision

In November, 1897, he again presented himself, very despondent "Vision" he said, "had again failed, had been so bad at times that he could hardly get about" He had abandoned business and was trying to take care of himself, had had some difficulty with his digestion, but had not consulted his family physician Sometimes he thought he saw better with the eye that had the cataract His face was pale and his manner was languid, but to my great surprise vision was more acute in the left eye than at his last visit With —7 sph (an increase 3D —) and — 0 75 cyl, axis 90 he had almost $^{20}/_{40}$ Tension was normal and the field was normal I made no change in his glasses, but insisted that he should see his family physician at once He came a month later, having in the meantime gone to see a physician in Chicago There he had gotten a diagnosis of enlarged prostate and chronic cystitis Urinalysis had shown the presence of pus and a little albumin, but no casts He had been advised to learn and practice self catheterization, and for this purpose had ordered a catheter He thought his vision was again worse, but I could see no change In January of this year his daughter wrote me that "vision had again failed, was just as good without glasses as with, and poor both ways The Chicago doctor had written that it was probably due to albuminuric retinitis, and the prospect was grave" I thereupon went to see my patient at his home I found him confined to his bed, very feeble and despondent, about ready to give up the fight His appetite had failed, the bowels were inactive, and he had the characteristic odor of the breath Vision was reduced to Q P L, and not improved by his glasses I dilated the pupil with homatropin and examined the fundus thoroughly, but no suggestion could I find of hemorrhage, or retinal inflammation The disc was possibly more excavated, but even that was doubtful Tension was normal In consultation with his physician I afterward learned that in attempting self catheterization, a silver catheter had been used, violence had been done, and an orchitis set up And this was the original cause of his going to bed As in case 1, I advised the free use of calomel and expressed my belief that the amblyopia was toxic, although probably not uremic in character How thoroughly my idea of treatment was carried out I do not know, for we were forty miles apart But I understand that it obtained in part at least with good results A month later my patient died The daughter, in writing to me of this event said the nurse described it briefly as 'death from uremia" But she also wrote these particulars "Six days prior to his death he had some friends in to play cards with him He had been up and around but was weak Three days before he died he began to suffer pain (I subsequently heard that this was in the lower part of the abdomen), and this was more or less continuous to the end The day before he died he was up and dressed, but in the evening had a terrible chill, an hour later became delirious, and went from that condition into coma which terminated fatally in a few hours" No autopsy

Case 3 —J W, age 35, a machinist in the railway shops, came to me Oct 6, 1897, to have a small foreign body removed from the cornea It was superficially lodged and easily extracted Otober 18 he returned to say that his injury of the 6th instant had been more serious than he thought, as he was unable to see the lines on his work The injured eye was perfectly healed, and had V=$^{-}/_{10}$—, while the uninjured eye had only $^{20}/_{30}$— The discs were a little pale, no other abnormality Hyperopia (under scopolamin) was 0 5D Glasses did not help His general health, he said, was good, except for a little indigestion and a little constipation He used tobacco freely, and drank weak domestic wine at home He also had a little difficulty in telling colors—confused reds and greens This proved not be a typic scotoma for color, but I nevertheless looked upon the case as a tobacco alcohol amblyopia and contented myself with advising total abstinence After a month of this, he returned to say that he was no better in vision, and now he had no appetite He was pale and anxious looking

All at once, in coming close to him, I caught the odor of his breath It was identical with that in Case 1 So I gave calomel to free catharsis, and followed this with calomel and salol in small doses, thrice daily, for a number of days Under this treatment the breath became sweet appetite returned and the bowels became regular On December 12 my record shows that he accepted a correction of +0 5 sph which he had before refused, and had $^{20}/_{30}$ + in both eyes

Case 4 —T G , age 12 years, schoolboy, son of a farmer, came home from school one day about the middle of last December, complaining of headache and inability to see his lessons He had been dull and listless for a week or two but prior to this had made no complaint I did not see him until he had been ill five weeks He had now been confined to bed since January 9, suffering from obstinate constipation, persistent vomiting, and pain in the head and eyes His bodily weight had fallen from 90 to 65 pounds, and he had an unnatural appetite—at one time craving, at another indifferent His vision had also failed

The boy was spirituelle in appearance, greeted me pleasantly, and answered questions willingly, in a subdued drawl General weakness was manifest, but there was no evidence of any paralysis and the reflexes were normal The tongue had a yellow and brown coat, and the breath was not sweet Vision was $^{10}/_{30}$ — in the right eye, and $^{10}/_{30}$ in the left—better with + 0 75 cyls (90 degrees) than without He professed inability to read any ordinary type, but read a few words in large type, held very close

The fundus, which I could see best (erect) with + 4 D correction (and I have hyperopia 2 5 D) had no markings that might not have been normal The inferior temporal vessels gave a suggestion of fullness and curving, and the pigment in one or two places was not evenly distributed But I could find no swelling at these points or about the papillæ As in the other cases, I advised a thorough exhibition of calomel, and careful supervision of the diet This advice developed the fact that in order to keep the bowels from complete inaction the cascara strychnin belladonna pill had been resorted to, and he was taking from three to five every night at bedtime The calomel, however, was given, as I afterward learned, and produced the most foul odored discharges that the family had ever known Following this there was a little amelioration of the conditions But the treatment was not pushed, and the benefit was temporary

I did not see this patient again until three months had elapsed Stimulated to more persistent effort by their family physician, wonders had been worked in the boy's general condition He is not yet able to walk, but he sits up all day, and is gaining in strength and weight His vision is also improving slowly He can tell the time by the wall clock and read a little Jaeger No 6 There is still nothing in the fundus, that I can see, to account for this defective vision

Extended comment seems to me unnecessary No one realizes more fully than I the incompleteness of the pictures herewith presented, and that there is nothing in these visual peculiarities which might not have been simulated nolens volens Had I seen but one, or, at most, two cases of this character I should not have so trespassed on your time and attention But the number of cases and the constant association of the visual disturbances with manifest disorders of digestion which were so nearly alike in all, has impressed me

I also deem it but justice to myself to say, that I had exclusive control in but one of the six cases and this is said with no intent to disparage my colleagues in the other five It only explains in part, the absence of systematic investigation for the moving cause Of the two cases not described, it remains to be said that one was a boy aged 10 years, the other, a man aged 27 years Both recovered

To recapitulate according to age There was one at 10, one at 12, one at 27, one at 40 and one at 63 Five males and one female

DISCUSSION ON TOBACCO AMBLYOPIA

Dr F C Hotz, Chicago—I was invited to open this discussion, but I take it that I need not cover the whole subject that has been presented, and that it is my duty simply to start the ball of discussion rolling My experience with toxic amblyopia has not been very large I have for instance, never seen a case of quinin amblyopia, or one from any other cause than tobacco and alcohol My cases were mostly of the mixed form, both alcohol and tobacco being used to excess by the patients From the observations that I made, I think the gradual loss of sight, the slight ophthalmoscopic change at the disc and the sluggishness of the pupils were the prominent clinical symptoms The patients do not, as a rule, come to us at an early stage, but I have among my cases one that is an exception, and I have not heard or seen anything like it In that case, the patient had good vision in the morning and two hours later his vision was completely obscured in both eyes He was a saloon keeper and was one of his best customers, both as to wet stock and the weeds He was secretary of a lodge, and one morning (this occurred in 1875) he wrote up the minutes of a previous meeting to report at the meeting to be held that afternoon He went to the meeting two hours later, and when the chairman called upon him to read the minutes, to his amazement he was unable to see his own handwriting

He came to Chicago two or three days afterward, and an examination showed slight blurring of the edges of the disc, the vision reduced to less than -$^{0}/_{100}$, and the perimeter showed a positive central scotoma in each eye, in the right covering ten degrees, and in the left five degrees He was advised, of course, to stop drinking and smoking at once, and to use the iodid of potassium in increasing doses, pushing it rapidly In a few months there was no trace of scotoma and central vision had improved to -$^{0}/_{0}$ In this case I am not quite certain whether the gentleman has absolutely followed out my orders as to the liquor, but I suspected all the time that he did not

We are often told by patients of the sudden loss of sight and find on closer questioning that vision had been failing gradually, and they reckon the loss only from the moment when they failed to read, but in this case there is evidence of the patient having been able to read and write two hours before the total failure

Dr Casey A Wood, Chicago—I have been especially interested in Dr Young's paper, because I believe that I have obtained ample evidence of the auto intoxication theory of amblyopia Horner—and I do not think there has ever been any more acute observer of these cases—as long ago as 1873 expressed the opinion that inasmuch as he had noticed chronic gastritis in alcohol amblyopia, so did he believe that the changes in the stomach had to do with toxic amblyopia quite as much as the tobacco or alcohol in the system Sachs, a short time ago, went even further and stated, I believe, that it is not the nicotine or alcohol but some compounds of these things in the stomach which produced the retrobulbar neuritis of toxic amblyopia

There are other points of interest we should not forget Amblyopia often comes on in diabetes, as a result of malnutrition Another point to bear in mind Tobacco does not set up changes in other nerves Another matter to consider in connection with this paper is that form of atrophy of the optic nerve that Uthoff placed among the unknown causes I have for several years held the belief that these cases were in some instances at least due to auto intoxication In talking the matter over recently with Dr Klebs and Dr Turck of Chicago, we all thought it was not impossible that this might be the case In a series of experiments on dogs recently it was noticed that in some instances, after hypodermic injection of certain ptomaines amblyopia followed We have continued these experiments, and I propose to follow them up and I suggest to you all the proposition that a certain class of cases of progressive optic nerve atrophy are the result of absorption from the intestinal tract

Dr D S Reynolds, Louisville—This is a field that is very fertile, I think, and it is fortunate that a large number of observers are cultivating it I have every reason to believe that there are many cases of amblyopia due to auto intoxication That view has been forced upon me by experience I am equally convinced that the cases of tobacco amblyopia are difficult to separate by any pathologic changes, by perimetry and the color test, from similar conditions found in persons given to the use of other toxic drugs. I do not believe that the use of alcohol alone, as a beverage, is so likely to produce amblyopia as the condition that it brings on by way of disturbed functions. The inhibitory effect of alcohol upon the eliminating organs affords, at least, reasonable grounds to suspect that a part of the results of amblyopia formerly attributed to alcohol are really due to auto-intoxication, because similar conditions are found in people with disturbed nutrition who do not use alcohol. There are many cases in which amblyopia at first may be very slight, and when you see the same again, say after a lapse of two or three years, you note that the area of affected optic nerve substance has gradually extended, and if symmetrically in all directions from the central point, there has been very little increase in the amblyopia, but if more extended toward the temporal side of the disc, then the amblyopia has been correspondingly increased.

I think I know that tobacco does produce a form of hyperplasia resulting in changes in the nerve structure, and I dissent from the view that it operates upon the optic nerve alone, because it is well known that those who use tobacco in any form have disturbances of muscular co-ordination, and are liable, most of them at least, to insomnia. The fact, too, that tobacco heart is a recognized form of weak heart, is another evidence that other parts of the body than the optic nerve are disturbed.

Now, I believe that the tea drinker is in just as much danger as the habitual consumer of tobacco, and that these are not in much greater danger than the excessive coffee drinker. I believe that coffee does not hurt any one who takes active exercise, and who takes the coffee in the morning only, but those who use it three times a day and often extra cups between meals, are apt to have trouble. I know a lady in Louisville who got in the habit of drinking coffee to such an extent that any intelligence of a disturbing character called for the use of more coffee, and she had such disturbances of muscular co-ordination that she became unable to stand alone. Her vision is so bad that she can no longer read, and can only see sufficiently to distinguish chairs and large objects about the room.

Dr. **Leartus Connor**, Detroit—At our meeting in Newport, I presented a paper on "Tobacco Amblyopia, Pure and Simple," and reported all the cases I could ascribe to a definite cause. Since then a few have come to my notice, and one of them was singular in this respect, that the man, 40 years old, began to smoke as soon as he could walk. His father was an inveterate tobacco user, and the boy was taught to light the pipe and smoke it before the father received it. No doubt it was a very pretty thing to the father, and the boy kept up the use of tobacco nearly constantly until about a month before I saw him, when he noticed a failure of vision. He was a very nervous man, but otherwise in perfect health, and he never used any alcohol, tea or coffee. Characteristic evidences of disturbance of the optic nerve were apparent; the vision in one eye 4/200, and in the other 2/200. When I told him what he had to do, he said: "I would rather die than do that, but for the sake of my wife I will try it." He did try, and in three months his vision was 20/30 in either eye and he could read J1. Some six months after this he met with financial difficulties, and in a fit of despondency killed himself. Whether the loss of tone to the nervous system rendered him unable to resist this action in the time of trouble I do not know.

I have never seen a case of quinin amblyopia, but a case came to me recently, a little child about 12 years old, who had the history of using three or four cups of strong coffee three times a day. For a month or two before her visit to me she had quite severe headaches, and her right eye finally became utterly useless for sight. Everything looked red before her and the right eye saw things imperfectly. If I held my hand before her, she saw it, but declared its position reversed from what it actually was. The ophthalmoscopic evidences were negative. The stopping of the coffee alone resulted in the diminution of these symptoms and the return of normal vision.

As I remarked to Dr. Reynolds, a few minutes ago, coffee has given me more trouble in the disturbances of vision than all the other drugs used by humanity put together.

Dr. W. H. **Wilder**, Chicago—I think there is a suggestion of considerable truth in the idea of auto-infection causing impairment of vision, but I can not believe that many of the so-called toxic amblyopias are cases of auto-intoxication. The cases reported present certain unique features, and it would seem to be difficult in many cases to dissociate the symptoms from hysterical manifestations. As far as intoxication with quinin, or any other drug than tobacco, is concerned, I have never seen but one well-marked case. I remember seeing one case of quinin amblyopia in a woman residing in the South who had taken very large doses of this drug for malaria. The general impression is, I think, that the ill effects resulting from the use of tobacco are due to nicotine, but I do not think this can be proven at all, but rather that the trouble is due to some other product of tobacco, possibly to the ingestion of pyridin. It has been shown that when tobacco is smoked in cigars, collodin is present in large percentage, whereas when it is used in a pipe pyridin is the main product which gains entrance into the system, and naturally we would expect more of it to be ingested the shorter the pipe. I believe it is a well-known fact that more of these cases of tobacco amblyopia are seen in England than elsewhere in the world, and it is probably due to the fact that the Englishman usually smokes a short pipe. That lends some support to the idea that it is pyridin that produces the ill effect.

Aside from all this, there is also the factor of susceptibility of the individual. We can not say in any given case that a man is likely to have an attack of tobacco amblyopia, and certain races, the Cubans and Spanish, for instance, are almost free from it. The use of certain qualities of tobacco also seems to produce more trouble than others. Aside from the susceptibility of the patient, I do not believe an individual is liable to an attack unless the resisting power of the whole organism is lowered, and then an excess of either tobacco or alcohol is liable to bring on disturbances of digestion and a lowering of the general vitality, together with an inflammation of the nerve.

Dr. D. C. **Bryant**, Omaha—I have had a case under observation for ten years that is very susceptible to quinin. It happens to be my brother-in-law and I have had a good opportunity to observe him. Dr. Wilder spoke of the difference in the influence of the drug according to whether the patient was or was not in good health, but this patient seems to be an exception to that rule. He first noticed his trouble ten years ago, when he was suffering with malaria or mountain fever in Western Kansas and had taken large doses of quinin. His vision became very poor, and as he expressed it, "he was seeing through a pin hole," the vision being reduced to a central point. In the course of a month he had a relapse of the disease and quinin was used again with the same effect. He left the ranch, came home and recovered entirely. In order to see what effect it would have upon his eyes, some time after recovery I gave him a dose of quinin. He was then in good health, but a dose of 15 grains would markedly reduce his vision.

Dr. **Reynolds**—Did it produce peripheral contraction or obliteration of the central vision?

Dr. **Bryant**—Peripheral contraction. It seems to be a clear case of quinin poisoning.

Dr. C. R. **Holmes**, Cincinnati—I have under my observation a case that was rather unusual. On a Sunday a message came to me to call at a certain house Not going to my office on Sunday, my assistant received the message and made the visit. He has been with me nine years, is a very capable man and has made some excellent drawings I mention that to show that he knows optic nerve changes when he sees them He found the man drunk and blind He had been to Washington, where he had been successful in securing a patent He had been reading on the train on the way home and he stated that having caught cold he sent for some whisky and quinin He got a pint bottle from a fourth class druggist in the neighborhood and had directions to take a certain quantity every hour or two After taking about half of it his vision failed and he became deaf The doctor made an ophthalmoscopic examination the following morning and found intense hyperemia of the disc He had the contents of the bottle analyzed and found nothing but quinin and whisky I urged upon the assistant to tell him to come to the private hospital for treatment He refused and did not send for me again for two weeks, when he said he could begin to see the outlines of the window and his hearing had returned Three weeks later he came for treatment but at that time there was complete atrophy and he was totally blind

Dr ELLETT—In regard to the cases reported by Dr Lautenbach in which the condition disappeared without cessation of chewing tobacco my former partner, Dr Minor, has gone him one better and reported eight cases that underwent perfect recovery without stopping either smoking or chewing Those cases have been rather extensively quoted, but I do not think anybody has profited by them to permit such things in their treatment The only thing I want to comment on is the age of his cases, which is in striking contradistinction to the literature of the subject I have only found ten under 30 years of age and none under 20

Dr LAUTENBACH—As regards the age of the patients I think there has been one case reported at 19[1] I called attention to another fact which is that I believe there is a large class of cases which if recognized at first are perfectly curable I think we can then use a method of treatment that will bring us through our difficulties Often, especially in hospital practice, our diagnoses are not made accurately enough and often the medicine prescribed and the hygienic directions given are such that the case becomes well—the case not being reported as a tobacco or toxic case, but perhaps simply as a refraction case needing tobacco or alterative treatment to overcome a depraved general condition

In regard to the matter Dr Wood spoke of, that it has not been demonstrated that there is any effect upon any other nerve than the optic, we allow in our public schools certain truths to be taught for which we are in part responsible, and you will find in the school books attention called to the arrest of growth, etc , produced by tobacco and alcohol If it is true that they do not affect other nerves than the optic we should see that things are properly taught For myself I believe that there is plenty of ground for the belief that other nerves are affected It is well recognized that by the withdrawal of tobacco in certain cases of deafness we get rapid improvement, and hence tobacco deafness is a recognized disease Certain heart cases too are said primarily to be due to inhibitory changes in the coronary arteries and I do not see any reason for doubting it Watch the chronic user of tobacco his walk and shuffling gait, and the conviction grows that other nerves than the optic are affected

In regard to the matter of tea, I think the prediction can be made today that ten years hence quite a number of our men will report cases positively due to tea drinking The Americans have been until recently using the Chinese tea, but now a Ceylon tea, which is far more powerful in its effects upon the nervous system, is displacing it and it is expected that the use of Chinese tea on account of its inferior flavor will soon be a thing of the past I am sure I have seen cases attributable to Ceylon tea It is my belief that the whole class of cases we have been considering are due to changes primarily in the nerve, or in the cerebral center, I do not know which, but they all act in the same way and bring about the same result

Dr YOUNG—In connection with my paper I have only to repeat what I said at the start that the cases were indeterminate in my mind I try to make a differentiation between hysteric amblyopia and those which are not I should be inclined to classify hysteric amblyopia, as those which by the effort of the patient could be overcome You know that in the true hysteric cases if you can get the patient's mind off the subject you can promptly restore vision I used the expression "*nolens volens*" because I do not believe there was anything in my cases that was present *volens* and not *nolens* One patient, 60 years of age, when I saw him last was unable to recognize me and to count fingers Treatment enabled him to see sufficiently well to play cards, and I do not believe his death was due to uremic poison, because no casts were found at any examination I am further fortified by the experience of a colleague recently A man with enlarged prostate died with symptoms of septicemia, and postmortem discovered a large perineal abscess that had given no evidence by swelling or pain prior to death My impression is that my case died from septic trouble due to the injury from self catheterization

In connection with the calomel treatment I want to say that in only one case did I have control of the exhibition of the calomel and I was unable to enforce upon my friends the necessity for and advantage of small doses of calomel In the cases that recovered I attributed the result more than anything else to small doses of calomel kept up for quite a period

I want to endorse what Dr Reynolds said as to the uncertainty of color sensations in amblyopia and also to say that at the Atlanta meeting two years ago I reported a case of relapsed amblyopia from excessive tea drinking The case of inverted image that Dr Connor spoke of I should think belongs to the true hysteric amblyopias

ON THE USE OF EPITHELIAL GRAFTS FOR REPLACING THE OCULAR CONJUNCTIVA

Presented to the Section on Ophthalmology at the Forty ninth Annual
Meeting of the American Medical Association held at
Denver Colo , June 7-10, 1898

BY F C HOTZ, M D

PROFESSOR OF OPHTHALMOLOGY AND OTOLOGY, RUSH MEDICAL COLLEGE
CHICAGO

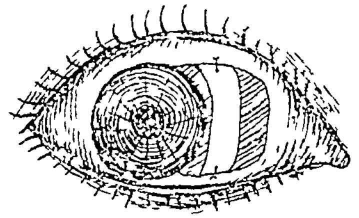
The unsatisfactory results obtained by the transplantation of rabbit's conjunctiva upon the eyeball, the laborious work of freeing from all shreds of submucous tissue the mucous flaps cut out with scissors or scalpels, and on the other hand, the ease with which Thiersch's skin grafts can be obtained and the certainty with which they grow in their new bed, have induced me many years ago to make use of Thiersch's grafts in operations for pterygium, symblepharon and other conditions where it was desirable to replace lost conjunctiva The results obtained by these operations were very satisfactory, the grafts answered the purpose for which they were implanted, in many instances they became after some time as smooth and glossy as the surrounding conjunctiva and though in other cases they continued producing a white coating of epidermis cells, I have never found this condition to cause any irritation Still I have always regarded the substitution of epidermis flaps for epithelial tissue as a make shift to be abandoned as soon as we should find a convenient method of obtaining epithelial grafts, for the ideal aim of our plastic work should be to replace mucous membrane by flaps of the same histologic character

---

[1] de Schweinitz—Toxic Amblyopias

I believe we have now that improved method we wished for, thanks to the ingenuity of the present chairman of this Section In the *Ophthalmic Record* of December, 1897,[1] Dr Gifford has shown that the cutting of epithelial grafts is very easy and successful if done with a razor instead of scissors or scalpels The flaps so cut, he says, correspond histologically for mucous membranes to the Thiersch's skin-flaps, they are cut so thin that only the epithelium and a very little of the subjacent tissue is removed In other words, Dr Clifford has solved the problem by applying the principle of the Thiersch's razor method of cutting skin grafts to the mucous membranes, an idea so simple that we can only wonder at that we have not hit upon it long ago

As to the proper execution of this new method I will quote Dr Gifford's own words "Probably the main reason why these thin lip-flaps have not been used more generally, is that it is hard to get at the lining of the lips so as to use a razor easily, and to facilitate the process I have had a large clamp made, of which the solid blade is smaller and set at an angle with the shank so as to pass clear through the fenestra of the other blade Closing the blade upon the lip forces the latter into a tense prominence from which the membrane can easily be shaved The surface must of course be kept wet and the razor must be sharp In cutting flaps to replace palpebral conjunctiva, it is better to cut them nearly twice as thick as where they are to be applied on the ball They should be slid directly from the razor to the denuded surface and there trimmed if necessary After pressing them down rather firmly with moist toothpick swabs, they should be allowed to dry on, so to speak, for two to three minutes before the lids are allowed to close A binocular bandage should be left on for the first twenty four hours, and after that a monocular for four or five days After a few days, a thin pellicle of epithelium is thrown off and what is left is so very thin and transparent that one is at first inclined to think that the whole flap has necrosed, but after some days it becomes evident that the flap is alive, although it is so much like the conjunctiva that its boundaries are hard to trace ’



Since reading Dr Gifford's article, I have employed his epithelial grafts in all cases where formerly I should have used Thiersch's grafts, and it gives me great pleasure to state that the results were so satisfactory that I have no reason to regret having substituted Dr Gifford's method for my own I found indeed the flaps could be cut very easily and accurately, and their application offered no difficulty if I only took care to keep track of the side which was to go down on the wound

For illustration I will report only one case, and I select the very first case in which I tried the new method, because it was a very severe test of its merits on account of the unusually large size of the flap

February 7 I removed from the eye of a young man an epithelioma of the ocular conjunctiva The very vascular growth surrounding almost the whole nasal margin of the cornea spread out 12 millimeters over the sclera and invaded the corneal epithelium about 1½ millimeters, the ocular conjunctiva adjoining the lower border of the tumor appeared thickened and opaque In removing this growth I first detached it carefully from the cornea, then I made an incision in the healthy conjunctiva all around it and finished with dissecting up the episcleral tissue from the conjunctival incision to the corneal margin The thickened portion of the ocular conjunctiva adjoining the lower end of the tumor was also excised This operation caused a large exposure of the sclera, which it was impossible to cover by a transplantation of the adjacent conjunctiva

I therefore decided upon implanting a Gifford's lip-graft As I had not Gifford's lip-clamp, I used our ordinary eyelid forceps with its fenestrated branch upon the mucous surface of the lower lip When the forceps was well screwed down the mucous membrane within the ring of the forceps was quickly anesthetized by holocain, and was so tense and prominent that the shaving could be done with the greatest facility and without the least pain I shaved off an epithelial flap about 1½ centimeters long and ½ centimeter wide This flap, floating in sterile salt solution, was transported on the razor to the eyeball and spread out over the denuded surface It was long enough to reach from the upper to the lower conjunctival border of the defect, but too narrow to cover its entire width I had purposely cut it so narrow because in my first grafting operations when the grafts were cut so large as to cover the whole width of the denuded surface, I usually found them slightly displaced toward the cornea during the first twenty-four hours, and I had come to the conclusion that this displacement occurred because the conjunctival border was in contact with the graft and pushing against it during every lateral rotation of the eyeball, displaced it more or less before it had become adherent When the graft is cut narrower so that a space is left between it and the conjunctival border, this displacement does not occur, because that free space prevents the conjunctiva from unduly crowding against the graft during the first twenty-four hours, and when later on the conjunctiva is drawn up closely to the graft, this has gained sufficient hold on the sclera that it can no longer be shifted from its place But to make doubly sure that this graft, which was unusually long, would retain its position, I fastened its upper and lower end to the conjunctiva near the cornea by very fine silk sutures After the eye had then once more been thoroughly irrigated with boric acid solution, both eyes were bandaged

On the second day the graft was firmly adherent, the sutures could be removed and the bandage left off At the end of the first week the gap between the graft and conjunctiva was closed, the conjunctiva having been drawn up to the longitudinal border of the graft In March, when the patient was shown at the meeting of the Chicago Ophthalmological Society, the graft was smooth and red like the adjoining ocular conjunctiva, and when later on the injection of the conjunctiva disappeared the graft also became pale and clear It showed no perceptible contraction, and only the closest inspection could find the dividing line of the graft and the ocular conjunctiva

[1] On the Use of Epithelial Lip flaps and Half Skin flaps in Eye Surgery ”

DISCUSSION

Dr W L Dayton, Lincoln, Neb —While in Chicago I had a conversation with Dr Hotz in which he mentioned one of his cases to me, and I determined to try this method at the first opportunity Last week a patient presented himself with a very large pterygium that extended clear over the center of the cornea, and fully 2 mm in width at its apex I resolved to make a mucous graft there from the lip I performed the operation as Dr Gifford has suggested, taking a flap 7 or 8 mm long and 5 mm wide In dissecting up the growth I dissected 4 or 5 mm back from the edge of the cornea and down to the sclera, but as he moved the eye suddenly the conjunctiva tore farther back I then had my assistant take hold above while I dissected it back to the caruncle and removed it, leaving the conjunctiva intact after having cut down to the sclera 5 mm from the limits This left a 5x8 mm space to fill up with the graft Everting the lip and outlining the size of the flap desired, I removed the graft with a razor, dropping a few drops of salt solution on the razor, and transferred the graft directly to the eye I held it in position by placing four sutures, one at either corner It was allowed to remain until the third morning, when the lower portion of the graft was of a beautiful rosy hue, and the upper portion a little white and slightly loosened I removed the stitches on Saturday last, and the graft had grown beautifully in its entire extent

In regard to the use of a local anesthetic, I would say that I have never tried the holocain, but I would not advise the use of any local anesthetic before shaving the graft, for I presume it does not hurt very much

Dr G C Savage, Nashville—My friend Hotz and I do not always agree, but I believe the best method for dealing with pterygium is that outlined in his paper Following Hotz, I commenced the transplantation of skin, instead of mucous membrane, and months and months after found it still skin, so I am glad to hear, from his own lips, that it is better to use mucous membrane My own method of operating is to make a puncture and counter puncture in the body of the pterygium, not far from the cornea, through these passing one blade of straight scissors, pressing the blades slightly toward the inner canthus before bringing them together, and pull off the corneal portion by traction forceps A very small portion of the mucous membrane of the lip transplanted will cover almost completely the exposed scleral wound One suture above will hold it in place, as a rule My experience from this method of procedure is very happy I think it should be resorted to in all cases, because so many of the cases operated upon by other methods recur

Dr J L Thompson, Indianapolis—How long have any of you gentlemen seen your cases after these operations have been done?

Dr Hotz—This case reported was operated upon in February, and I saw him two weeks before I came here This was not a pterygium case, however, but I think the same operation applies I have seen cases treated with the Thiersch graft two years afterward, and the growth had not returned

Dr Gifford—There is very little to be said except that the suggestion of Dr Hotz, that where you have a large flap it is better to use a stitch, is a good one It is a good plan to dissect up the conjunctiva so as to tuck the flap under, and stitch above and below

With regard to the length of time after they have been operated on, I have one case that I have watched for three years The eye does not look natural in every way, but the pterygium has not returned, and as it was a malignant case that had recurred five or six times, I was glad to get any kind of a result.

REGULAR CORNEAL ASTIGMATISM IS NOT ALWAYS CONGENITAL NEITHER IS IT UNCHANGEABLE

Presented to the Section on Ophthalmology at the Forty ninth Annual
Meeting of the American Medical Association held at
Denver, Colo June 7 10 1898

BY WILLIAM C BANE M D

Late Ophthalmologist to the Chair of Neurology and Chief Clinical
Assistant in Ophthalmology and Otology in the Medical Depart
ment of the University of Colorado Ophthalmologist
and Otologist to the House of the Good Shep
herd Oculist and Aurist to the
C R I & P Ry
DENVER COLO

That regular astigmatism of the cornea is not always congenital, is clearly stated in some of our standard text-books on ophthalmology Noyes (2d rev ed, p 111) states that "some rare cases of regular corneal astigmatism are acquired, but as a rule the affection is congenital" Schmidt Rimpler (3d ed p 84) believes "as a rule the affection is congenital" Berry (2d ed, p 543) says of astigmatism "The cause is mostly a difference in the curvature of different meridians of the cornea, a difference which may be congenital or acquired"

Hartridge (Refraction of the Eye, p 122) expresses the view "astigmatism is usually congenital, but may be acquired, and frequently there is some hereditary tendency' Henderson (Annals of Ophthalmology and Otology, Vol v, p 523) has reported one case of acquired regular corneal astigmatism The literature bearing on acquired regular corneal astigmatism is certainly very limited To be convinced that regular corneal astigmatism is not always congenital necessitates refractive work on the same persons for many years, during which re examinations of eyes are made, and the measurements compared The same rule applies as to the permanency or unchangeableness of regular corneal astigmatism, whether in amount or meridian I have selected two cases to illustrate the subject

Case 1 —Illustrating the Development of Regular Corneal Astigmatism E B, a girl, aged 10 years Referred by Dr Eskridge, Feb 18, 1892 History of pain in her eyes and frontal headache almost every day, while using her eyes for close work in school General health good

V R = 6/6 V L = 6/6 Pupils are equal and respond normally to light and accommodation Fields are normal Manifest 2° Esphoria

Accepts +0 50 s for each eye, with vision of 6/6 Radiating lines on the dial equal Homatropin used as a cycloplegic, under which V with +1 s R, and L = 6/6 At confirmatory test, two days later, +0 50 s was ordered for constant wear Patient returned Oct 21, 1893, twenty months after first examination, and complained that her eyes were not comfortable Another examination was made under homatropin and atropin, with the result that under the cycloplegic she accepted +1 s for each eye giving vision of 6/6 No manifestations of astigmatism On Sept 16, 1896, *four and one half years after the* first examination, patient returned complaining of her eyes aching upon use for close work and occasionally frontal headache She has developed rapidly, changing from girlhood to young womanhood

V R = 6/9 —, V L 6/12 + Pupils, accommodation and fields are normal Fundi are healthy in appearance Hotz' Astigmometer indicated 0 50 D astigmatism axis, 180° in each eye.

O D —0 50 c 180° 6/5 Lines on dial normal

O S —0 75 c 180° 6/6 Accommodation paralyzed with Wyeth's ophthalmic discs of homatropin and cocain

O D +0 75 s ⌢ — 0 50 c 180° 6/5

O S +0 75 s ⌢ —0 50 c 180° 6/6

After twenty four hours a confirmatory test was made and patient accepted —0 50 c 180° for each eye givin[illegible] r vision of 6/[illegible] and equalizing the lines on d[illegible] later the test was repeated, with exac[illegible] the above cylinders were ordered

This patient came under my [illegible]

gan wearing the cylinders, suffering with an attack of pharyngitis, at which time she reported that her eyes were comfortable, and that she had worn the spectacles constantly

Case 2 —Illustrating a Change in the Astigmatism, eight years elapsing between the examinations W J, aged 24 years Referred by Dr John Mahon of Allegheny City, Feb 11, 1889 History of indistinctness of vision, especially on reading, and occasional attacks of frontal headache after reading for about an hour The eyelids are inflamed and the margins thickened, some crusts adhering about the roots of the lashes

V R =6/6, L =6/6 Pupils equal and react normally to light and accommodation Fields for white normal

O D —0 50 c 165°=6/6
O S —0 60 c 15°=6/6

An eight grain solution of homatropin used as a cycloplegic

O D +0 50 s ⌒ —0 50 c 160° =6/6
O S +0 50 s ⌒ —0 75 c 10°=6/6

At confirmatory test he accepted

R —0 60 c 160°=6/6 Dial normal
L —0 75 c 10°=6/6 Dial normal

Prescribed two grain ointment of the yellow oxid of mercury for the blepharitis

On May 17, 1897, while in Pittsburg, W J came to me for re examination He stated that his eyes had not troubled him since 1889, when he began wearing the spectacles, until within the past year The blepharitis is well and has been for several years Recently he has experienced some aching of his eyes and pain in his right temple Vision less distinct than formerly

V R =6/10, L =6/20
O D —1 c 160°=6/6
O S —2 c 180°=6/6

Wyeth's discs of homatropin and cocain used as a cycloplegic

O D +0 50 s ⌒ —1 c 160°=6/6
O S +0 50 s ⌒ —2 c 180°=6/6

May 19, 1897, prescribed

O D —0 75 c 160°
O S —1 75 c 180°

The change that had occurred was a slight increase in the astigmatism in the right eye and one diopter increase in the left eye, with a change of ten degrees in the meridian of the left eye

The first case is one in which the astigmatism developed during the stage of rapid growth of the body It seems reasonable to me that we might expect some change in the shape or length of the eye, as occurs in other organs of the body during the period of rapid growth It is the age when myopia does develop and increase

It will be noted that both the cases I have reported are cases of myopic astigmatism The one reported by Dr Henderson changed from emmetropia to myopic astigmatism

One point naturally comes in here for consideration, i e, can we say to our patients under 40 years of age that no change will be required in their glasses until presbyopia becomes manifest? With me, and I presume it has been the experience of others, not a little of my refractive work has been the measurement of eyes that have already been measured by other physicians In not a few cases I have found that the glasses ordered for the patients were not suitable They may have been of the proper focus at the time ordered and the eyes have changed in the meantime Hence it becomes us to be on our guard to avoid criticising a brother practitioner's work, when our findings do not correspond

It is a question as to what proportion of the cases I have seen, that were not wearing proper glasses, was due to improper correction and what proportion due to changes in the eyes I know some physicians will hold that the errors in the class of cases I have reported were not corrected in full at first I admit such mistakes are made, and I presume I have made some of them We have cases of amblyopia, in which it is quite impossible to be positive of the accuracy of our correction, even with all the modern methods and appliances

If, with this brief presentation of the subject, we may have a free discussion of it by the members who have had an extensive experience in refractive work, and their views placed on record, my object in bringing this subject for your consideration will have been attained

Steele Block, 16th and Stout Sts

DISCUSSION
